INDEX TO VOLUME I FOR 1931

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, *X* Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Pyelography and Urography; Lunacy and Mental Diseases; Sunlight and Ultra-violet; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

Abdomen, lower, pain in (W. Fletcher Shaw), 269
Abdominal diagnosis. *See* Diagnosis
Abdominal emergencies, earlier diagnosis of, (C. H. Fagge), 50 (O)
Abdominal injury, an unusual (D. M. Sutherland), 264
Abdominal symptoms, acute, Meckel's diverticulum as the cause of (A. Harvard Baker), 252 (O). *See also* Diverticulum
Aberdeen. *See* Scotland
ABERNETHY, Christine: Two cases of syphilitic spondylitis, 1112 (O)
Abernethy, John (1764-1831), 718, 719
ABRAHAMSON, Leonard: Treatment of psychoneuroses, 17
Abrodil for intravenous pyelography, 20, 625
Abscess, brain. *See* Abscess, cerebellar
Abscess of breast, 480, 524
Abscess, cerebellar (Courtenay Yorke), 891 (O)—Correspondence on, 1001, 1043, 1139
Abscess, subphrenic (W. D. Doherty and R. P. Rowlands), 163 (O)—Correspondence on, 241, 770
Abscess, subphrenic, simulated by hydatid cyst of liver (E. H. R. Altounyan), 15
Académie de Médecine: Expresses the opinion that public exhibitions of hypnotism are undesirable, 163—The B.C.G. controversy, 861—Antitetanic serum, obligatory use of, 861—Etiology of disseminated sclerosis, 943

ACADEMY, ROYAL, OF MEDICINE IN IRELAND:
Section of Laryngology and Otology.—Bilateral abductor paralysis, 270 — Laryngofissure for epithelioma of the vocal cord, 270—Splint for use in operation for septal resection, 270—Retrosternal goitre, 270—"A retrospect of laryngology," 270—Intracranial complications of ear disease, 937—Papilloma of the right vocal cord, 937—Vallecular dysphagia, 937—Abscess of temporal lobe, 937—Epithelioma of fauces treated by diathermy, 937—Operation for lateral sinus thrombosis, 937—Temporal lobe abscess, 937
Section of Medicine.—Treatment of psychoneuroses, 17—Oedema and nephrosis, 586
Section of Obstetrics.—President's address: Puerperal sepsis, 99—Analgesia in labour, 669
Section of Pathology.—Unusual tumours, 401—Myelomatosis, 401—Tumour of neck—malignant endothelioma (?), 402—Unusual renal tumour, 402
Section of Surgery.—Treatment of fractures, 31—The role of plastic surgery, in the treatment of lupus vulgaris, 403—Spontaneous perforation of jejunal ulcers, 541—Spinocain anaesthesia, 541—Popliteal aneurysm, 708—Spontaneous rupture of the spleen, 708

Accident prevention (Eric Farmer), 716
Accidents, aircraft, number of (parliamentary notes), 959, 1143
Accidents [illegible] L.C.C. reply to a [illegible] shock following, [illegible] tate), 512
[illegible] *ema of Bright's* [illegible] ppointed a com- [illegible] our, 567
[illegible] from the clinician's point of view (Leonard Findlay), 433 (O)
Acidosis and seborrhoea (John T. Ingram and F. S. Fowweather), 839 (O)—Correspondence on, 914
ACLAND, Theodore Dyke, obituary notice of, 729
Acriflavine in midwifery. *See* Midwifery, prophylaxis in
Acrocyanosis (Fernand Layani), 364
Acta Medica Scandinavica:—*Supplementum* [illegible]: *Diätetische Behandlung des runden Geschwürs des Magens und des Duodenums* (Alexander Jarotzky), 1075
Actinotherapy, equipment for, 103
Actinotherapy [illegible] 42 [illegible] rtificial; Sun- [illegible] : C.I.E. conferred on, 73—Pathology and treatment of sprue, 222
Actuaries, Faculty of: The selection of lives, 189

Sierra Leone, a survey of disease in, 1125
Silicosis in South Africa, 1053
Socialist medical conference, 1035
Society of Apothecaries, 232, 762—Its roll of
Surgery, present-day, glances at, 107
Surgical Research Institute, 320
Tavistock Square Clinic, 855
Taxation of learned societies, 278
Thallium and its risks, 320
Trachoma prize, International, 411
Tubercle bacillus, fractional products of the, 411
Tuberculosis, post-graduate courses in, 907
Tuberculous patients, after-history of, 191
Type cultures, national collection of, 1031
Typhus research in Malaya, 505
Undulant fever in the United States, 807
University of London's new buildings, 1033
Veterinary Bulletin, 762
Veterinary operations, 677
Vitamins in bread, incorporation of, 678
Vitamins, recent research on, 591
Vitamins and subacute combined degeneration of the cord, 409
Vitreous, the nature of the, 191
Wassermann reaction, 1124
Whooping-cough statistics, 107
X-ray unit for ambulance work, a new, 321
Yellow atrophy of the liver, acute, 277
Yellow fever, direct transmission of, 117

Weir, Henry Bricht, obituary notice of, 871
Weiss, Paul: High carbohydrate diet in diabetes, 310
Welch, William Henry, Hatben gold medal presented to, 960
Wellcome Foundations Ltd. to erect a new medical and chemical research building in London, 295
Wellcome, Henry, Honorary Freedom of the Society of Apothecaries conferred on, 232
Wellcome Museum of Medical Science closed for rebuilding, 205
Wells, Dr.: Rickets and oral sepsis, 232
Wells, light, efficiency of, 105. *See also* Light
Welsh Board of Health, functions transferred to, 765
Welsh. *See also* Wales
Wenckebach, K. F., to investigate the pathology of the heart in beri-beri at Batavia, Java, 523
Werner-Kümmell, Professor, death of, 428
West Riding Panel Record, 107—Glances at present-day surgery, 107
Wexford County, diphtheria immunization in, 199
Wharry, H. Mortimer: Case of "black" tongue, 664 (O)
Wharton, Denis R. A.:—*The Cat in Relation to Disease Transmission: A Review*, 907
Wheeler, Sir William I. de Courcy:—Tumour of neck: diagnosis a difficulty, 402—Unusual renal tumour, 402—Dublin Hospitals: a suggested commission of inquiry, 862—An anæsthetic screen, needle, and thimble as "surgical aids," 975 (O)
Whipple, G. H., awarded a prize for his work on the liver treatment of pernicious anæmia, 431
Whitaker, James Smith, knighthood conferred on, 25, 70
Whitby, H. A. Morton: Glycerin as a surgical dressing, 205—Acute urethritis in mumps, 868
Whitchurch, Arnold: Appreciation of Stephen John Ross, 517
White, P.: The diabetic child, 105
White, R. Presser, elected an honorary member of the Vienna Dermatological Society, 691
White, Winsbury: The radiological renal outline, 183
Whitfield, Arthur: The transmission of scabies and ringworm, 351—Sensitiveness to sunshine, 568
Whittingham, Wing Commander H. E. (and others): Observations on an outbreak of cerebro-spinal fever in the Royal Air Force in 1931, 1101 (O)
Whooping-cough: Statistics, 107—With inspiratory stridor (I. M. Benjamin), 180
Widdows, Sibyl T.: Aberrant mammary secretion, 870
Widows' pensions. *See* Pensions
Wiesner, B. P.:—Pregnancy Diagnosis Station: Report on second years' working, 860
Wigham, J. T.: Myelomatosis, 401
Wigley, J. Gardiner: The obstetrical problem of the contracted pelvis, 836

Wilkie, D. P. D.: Mortality in acute appendicular disease, 253 (O), 471—Appointed a member of the Scottish Scientific Advisory Committee, 471—*To act as Director of the Surgical Professorial Unit at St. Bartholomew's Hospital*, 991
Wilkinson, John F.:—Treatment of pernicious anæmia with hog's stomach: report of 103 cases, 85 (O), 595
Wilkinson, W. Camac: Tuberculin and the tuberculosis problem, 155—*Tuberculin clinic*, 206—The modern conception of early phthisis, 818—Acute massive collapse following lipiodol injection, 1047
Willcox, Sir William: *The choice of an anæsthetic*, 255—Lumleian Lectures on toxic jaundice, 557, 595—Action of avertin on the liver, 1021—*Diathalin in toxæmia*, 1021
Williams, E. Roland: A simple gas and oxygen apparatus, 675
Williams, Very Rev. Garfield Hedder, appointed to the Deanery of Manchester, 991
Williams, Gwynne: *Minor Surgery and Bandaging*, twentieth edition, rev., 757
Williams, J. E.: Routine anæsthesia in midwifery, 474
Williams, Jesse Feiring (and William Leonard Hughes): *Athletics in Education*, rev., 314
Williams, Leonard: The enigma of the chilblain, 320
Williams, R. M.: Two cases of haemorrhagic paratyphoid fever, 1057 (O)
Williams, R. Stenhouse: Nutritional value of milk, 1048
Williamson, Bruce (and A. J. Gibson): Undulant fever in infancy, 745 (O)—*A Handbook on Diseases of Children*, rev., 992
Williamson, G. Scott (and James H. Pratsel): *The Case for Action*, rev., 357
Willmore, J. G.: Treatment of intestinal amœbiasis, 847
Willis, Lucy: Treatment of "pernicious anæmia of pregnancy" and "tropical anæmia," 1059 (O)
Wilson, Claude: Medical charities, 32
Wilson, D. R.: Industrial lighting, 703
Wilson, George Ewart: *Fractures and their Complications*, rev., 1027
Wilson, Hector McLean, obituary notice of, 33
Wilson, I. G. H., appointed a commissioner of the Board of Control, 232
Wilson, J. St. George: Anæsthesia in childbirth, 437—Lower segment Cæsarean section, 733—Uterus spontaneously ruptured during unassisted delivery, 733
Wilson, S. A. Kinnier: Mental symptoms associated with brain tumours, 311—Prevention and treatment of drug addiction, 497—Appreciation of Sir Byrom Bramwell, 825
Wilson, T. G.: Bilateral abductor paralysis of the vocal cords, 270—Intracranial complications of ear disease, 937—Case of temporal lobe abscess, 937
Wilson, T. Stacey: Backache in women, 472—Blood pressure and life assurance, 816
Winnacs, A.: Recent advances in the chemistry of the vitamins, 1116
Wine, medicated, advertisements of (parliamentary note), 49
Winton, F. R. (and L. E. Bayliss): *Human Physiology*, rev., 59
Wireless coastal station "Lübe Weser-Radio" established in Germany by which any ship can obtain medical advice, 1039
Wise, Kendrick Stanton, appointed a member of the Executive Council of the Colony of Trinidad and Tobago, 335
Wolbach, S. B.: A correction *re* spelling of his name, 1100
Woldian duct, complete, persistence of (James Troup), 707
Wood, Alexander: The procedure of the hypodermic injection, 336
Wood, Mrs. Fred, death of, 652
Woodall, Ambrose Edgar, knighthood conferred on, 25, 70
Woodhard, Adelaide, Kaisar-i-Hind medal conferred on, 1034
Woodhouse, Christopher, coat of arms of, 779, 877
Woodhouse, Major-General Sir Tom Percy, obituary notice of, 699
Wood's glass in the diagnosis of ringworm (John Kinnear), 791 (O). *See also* Ringworm
Woods, Sir Robert: Splint for use in the operation of sental resection, 270—A retrospect of laryngology, 270
Woods, R. R.:—Tumour of neck: diagnosis difficult, 402—Vallecular dysphagia, 937—Abscess of temporal lobe, 937
Woodside, C. J. A.: Perforations of jejunum, 667
Woolbridge, G. H.: Radiological problems in veterinary medicine, 16—The transmission of
uses of
Woolwich, new housing estate and health centre at, 236
Workmen's compensation: Medical referees in Lanarkshire (parliamentary note), 650
Workmen's Compensation Act, nurses and other employees at isolation hospitals and (parliamentary note), 556—Medical referees (parliamentary note), 1098
Workmen's Compensation Bill, 771, 822, 916
Worms, schistosome, and schistosome monsters, 817, 914. *See also* Schistosome

WORSTER-DROUGHT, Dr.: Mental symptoms associated with brain tumours, 311
Wounded and sick in warfare, new international convention for the care of, 597
Wrapping for medicine bottles, 1056
WRIGHT, A. Dickson: Treatment of varicose ulceration, 330—Indolent ulcers of the leg, 398
WRIGHT, A. F.: Vaccine therapy, 355
WRIGHT, Sir Almroth: Indolent ulcers of the leg, 398
WRIGHT, E. Jenner: *The A and B Avitaminosis*
Madras
notice
WRIGLEY, A. J.: The obstetrical problem of the contracted pelvis, 896
WRIGLEY, Philip R.: Pain in the lower abdomen, 269
Writing with left hand, 163. *See also* Hand

London:

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION, TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME I, 1931

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

ABADIE, J.: Hydatid cysts of lung, 316
Abdomen, actinomycosis of, 348
Abdominal symptoms in acute rheumatism, 142
ABESHOUSE, B. S.: Post-operative urinary incontinence, 32
Abortion, treatment of, 256
Abscess, peritonsillar, treatment of, 501
ABT, A. F.: Percutaneous diphtheria immunization, 355
ABUREL, E.: Anaesthetization of the lumbo-aortic plexus, 580
Accouchement, rapid, by method of Delmas, 23. *See also* Labour
Achlorhydria with hypochromic anaemia, 438
Acid-base balance and allergy, 160
Acid production by Brucella strains, 488
Acne, an endocrine factor in, 403
Acoustic nerve. *See* Nerve
Acriflavine: In psoriasis vulgaris, 62—In undulant fever, 59
Actinomycosis of the abdomen, 348
Actino-sensitivity of oestrin, 542
ADDESSI, G.: Histamine and utero-placental apoplexy, 642
Addison's disease: The cortical hormone in, 15—Etiology of, 295—*Treatment of* with a hormone from the cortex of the suprarenal gland, 352
Adenitis, cervical, acute, tonsillectomy in, 195
Adenitis, inguinal, special form of, 94. *See also Lymphogranulomatosis*
Adenoacanthoma of the uterus, 210
Adenocarcinomatous growths of the bladder, 147
Adenoids in adults, frequency of, 275
Adenomatous goitres, 246
ADLERSBERG, D.: Local treatment of ulcers *with insulin*, 13
Adnexal inflammation, conservative operation for, 254
Agranulocytosis, 564
Alcoholic delirium, strychnine in, 375
Alcoholism, bactericidal power of the blood in, 262
ALDRIDGE, F. C.: An outbreak of trichinosis in Pennsylvania, 413
ALEMI, M.: Laryngeal complication of quinsy, 379
ALEXANDER, J.: Treatment of non-tuberculous pulmonary conditions, 72
Alkalis in malaria, the haemic effects of quinine and, 43
ALLEN, I. M.: *Tumours involving the cauda equina*, 174
ALLEN, P. K.: Acriflavine in psoriasis vulgaris, 62
Allergic syphilis. *See* Syphilis
Allergy and the acid-base balance, 160
Allergy conditions, skin tests in diagnosis of, 218
Amato's test for syphilis, 25
Ambulant therapy in proctology, 418
AMES, C. R.: Plasmoquine in malaria, 454
Amniotic bands, foetal injury by, 21
Amoebic colitis. *See* Colitis
[illegible] clerosis
[illegible]
Anaemia, hypochromic, with achlorhydria, 438
Anaemia, iron treatment of, 250
Anaemia, malarial, *splenic extract in*, 199
Anaemia, pernicious, 221—Liver diet in, histological effects of, 213—Resistant to liver treatment, 412
Anaemia, pernicious, the erythrocyte in, 335
Anaemia, pernicious, essential, pathogenic factors in, 315
Anaemia, pernicious, gastric juice of dogs in treatment of, 377—Gastric tissue of swine in, 424
Anaemia, splenic, local vascular changes in, 119
Anaemias, haemolytic, 137
Anaerobic blood culture. *See* Blood
Anaesthesia, combination, 154
Anaesthesia, effect of on paroxysmal conditions, 466
Anaesthesia, general, ethyl chloride, for children, 357
Anaesthesia, general, pulmonary complications of, 39
Anaesthesia, infiltration, in fractures, 153
Anaesthesia, intravenous, barbitone derivatives in, 37
Anaesthesia, local, percaine as a, 152
Anaesthesia, regional, 480
Anaesthesia, spinal: Indications for, 356—*Amytal in*, 482
Anaesthesia. *See also* Narcosis *and* Analgesia
Anaesthetic, general, for children, ethyl chloride as an, 357
Anaesthetic, pernocton as an, 353
Anaesthetic, spinal, neocaine as a, 603
Anaesthetization of the lumbo-aortic plexus, 580
Anal chancre, 555
[illegible]n, 505
[illegible]
Aneurysm of aorta, dissecting, simulating pulmonary neoplasm, 584
Aneurysm of the heart, diagnosis of, 93
Aneurysms, miliary, of cerebral arteries, 24
ANGELERI, C.: The titre of isoagglutinating serums, 386
ANGELINI, V.: Measles complicated by diabetes insipidus, 92
Angina pectoris, 511—*Surgical treatment of*, 302
ANGYAL, A.: The bactericidal power of the blood in alcoholism, 252
Anhydraemia in extensive superficial burns, 10
Ankle fractures, with backward dislocation, 395
Ankylosis of the temporo-maxillary joint, 592
Antigangrene serum in scarlet fever, 571
Antigens in *B. anthracis*, multiplicity of, 138
Antimony in therapeutics, 104
Antimony, organic, in kala-azar, 328
Antiseptics, influence of soap on, 487
Antral (Highmore) diseases, radiography in, 556
Aortic aneurysm. *See* Aneurysm
Apoplexy, utero-placental, and histamine, 642
Appendicectomy, the latero-posterior incision *for*, 549
Appendicitis, chronic, 274
Appendicitis in the middle-aged, 8
Appendicitis and trauma, 126
Arborescent lipoma. *See* Lipoma
Argyrosis of the cornea, 575
ARNHEIM, E. E.: Neocaine as a spinal anaesthetic, 603
ARONSTAM, N. E. Cutis marmorata (livedo reticularis), 252
Arsphenamine: Precautions during administration of, 497—In the treatment of syphilis, 526, *601*
Arterial hypertension: Rational treatment of, 73—Bismuth subnitrate in, 201—Treatment of *idiopathic*, 325
Arteries, cerebral, miliary aneurysms of, 24
Arthritis, chronic, treatment of, 524
Arthritis, infectious (atrophic), streptococci in, *89*
Arthritis, purulent, of the knee, treatment of, 419
Arthritis, syphilitic, 545
Artificial feeding. *See* Feeding
Artificial pneumothorax. *See* Pneumothorax
ARVANITAKIS, G.: Radiography of discrete pulmonary lesions, 427
Asbestosis bodies in the sputum, 161
Aschheim-Zondek test for pregnancy, 639
Ascites, a confirmatory physical sign in, 587
Ascites, foetal, 610
ASLETT, E.: Treatment of malaria, 598
Aspergillosis, cerebral, 367
Asphyxiation, neo-natal, 429
Asthma, bronchial, effect of anaesthesia on, 466
Asthma intensified by liver therapy, 295
Asthma, sex and age incidence in, 265
Astrocytomas, cerebellar, 345
AUDEBERT: Fibroma praevia and forceps delivery, 207
Auditory meatus, acute inflammation of the, 502
Auricular fibrillation in heart disease, 183
Auscultatory sign of defective conduction in mitral stenosis, 622
AVERILL, L. C. L.: Induction of labour, 156
Avertin causing fatal colitis, 602
AXELROD, M. L.: The barbiturates in obstetrical analgesia, 505
Axillary vein. *See* Vein
Azotaemia and renal insufficiency, 211

British Medical Journal

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

Including an Epitome of Current Medical Literature.

WITH SUPPLEMENT.

No. 3652. SATURDAY, JANUARY 3, 1931. Price 1/3

ERYTHGEN
LIVER EXTRACT

A highly potent derivative of fresh liver containing the hematopoietic principles recently introduced in the treatment of anaemias.

Erythgen Liver Extract

permits the treatment of anaemias with the active principles in place of large quantities of liver.

Bottles of 8 oz. solution. Bottles of 100 capsules.

Dose: 1 to 4 teaspoonfuls three times daily.
1 to 4 capsules three times daily.

G. W. CARNRICK CO.

Dependable Gland Products.

2-24 MT. PLEASANT AVENUE, NEWARK, NEW JERSEY.

London Agents: BROOKS & WARBURTON, LTD., 232/240, Vauxhall Bridge Road, S.W.1.

D & G Sutures

are always sterile

...under the most rigid bacteriologic methods ever devised for testing catgut.

C. F. THACKRAY - PARK ST., LEEDS - 252 REGENT ST., LONDON, W.1.

D & G SUTURES ARE ISSUED FOR USAGE UNDER MINISTRY OF HEALTH LICENCE 032 C

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks; ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

Just Issued

Arey's Developmental Anatomy

New (2nd) Edition

A revision so extensive, so thorough, so radical that the book is really brand new. Each chapter was replanned and rewritten; 435 additional new illustrations were added; a much fuller treatment of general development was given; a more complete discussion of specific malformation was included; and a number of new charts and tables.

Wherever at all possible—and this has been found much more so than formerly—the human embryo has replaced, in the study, that of the lower animals. This edition stands to-day as an outstanding accomplishment in its field. It is a book of 560 pages, with 1,037 illustrations on 532 figures.

Dr. Arey gives the student not only a complete descriptive text of embryology, but also a very practical laboratory manual. The first section treats of the early stages of development and outlines clearly the course of prenatal and postnatal development. The second section traces the origin and differentiation of the human organ systems, grouping them according to germ-layer development. The third section consists of a laboratory manual for the study of the pig and chick embryos.

Large octavo of 560 pages, with 1,037 illustrations on 532 figures. By LESLIE BRAINERD AREY, Robert Laughlin Rea Professor of Anatomy, Northwestern University Medical School. Cloth 27s. 6d. net.

Andrews' Diseases of the Skin

NEW

"The whole volume is excellently got up, and, considering the amount of matter contained in it, remains moderate in size and easy to handle. We commend it with confidence both to general practitioners and specialists."—BRIT. MED. JOUR.

By GEORGE C. ANDREWS, A.B., M.D., Associate Professor of Dermatology, College of Physicians and Surgeons, Columbia University, etc. Octavo of 1,091 pages, with 958 illustrations. Cloth, 55s. net.

Babcock's Text-Book of Surgery

A STANDARD

"Takes a distinguished place among the many general text-books that are available. It is designed both for the student and the practitioner, as the author believes that, with the increase of clinical teaching and the declining importance of systematic lectures, the student must turn more to his reading for his theoretic background."—BRIT. MED. JOUR.

By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Octavo of 1,367 pages, with 1,050 illustrations, 9 in colours. Cloth 45s. net.

Maximow's Text-Book of Histology

NEW

"The book is one which can be recommended with confidence as a general work of reference for the more advanced student of this branch of study."—BRIT. MED. JOUR.

By ALEXANDER A. MAXIMOW, late Professor of Anatomy, University of Chicago. Completed and edited by WILLIAM BLOOM, Assistant Professor of Anatomy, University of Chicago. Large octavo of 833 pages, with 604 illustrations, some in colours. Cloth, 40s. net.

Ranson's Anatomy of Nervous System

3rd EDITION

"The book provides a useful foundation in macroscopical and microscopical anatomy, considered always with an eye to the physiological correlates of given structures, thus supplying a dynamic as opposed to a static presentation. It is wonderfully complete, and for the novice in neurology it should prove highly serviceable."—LANCET.

By STEPHEN W. RANSON, M.D., Professor of Neurology, Northwestern University Medical School, Chicago. Octavo of 425 pages, with 284 illustrations, some in colours. Third, Revised, Edition. Cloth 32s. 6d. net.

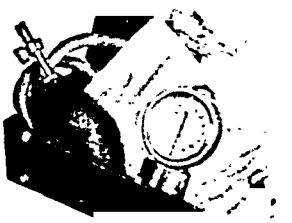
As necessary as a Stethoscope

The present-day physician can ill afford to dispense with a sphygmomanometer as part of his visiting equipment. Many of the greatest medical minds of to-day advocate blood pressure tests as a guide to the eventual diagnosis.

The question of portability is easily solved by the S. & M. Portable type of Sphyg. as illustrated. This instrument—including Patent Arm Sleeve and Inflating Bulb with Control Valve—is contained in a leather carrying case 7 in. long, 4 in. wide by 3 in. deep.

Write for full details and prices.



Every genuine instrument bears the trade-mark "Tycos" engraved on the dial.

Obtainable from all reputable Instrument Dealers.

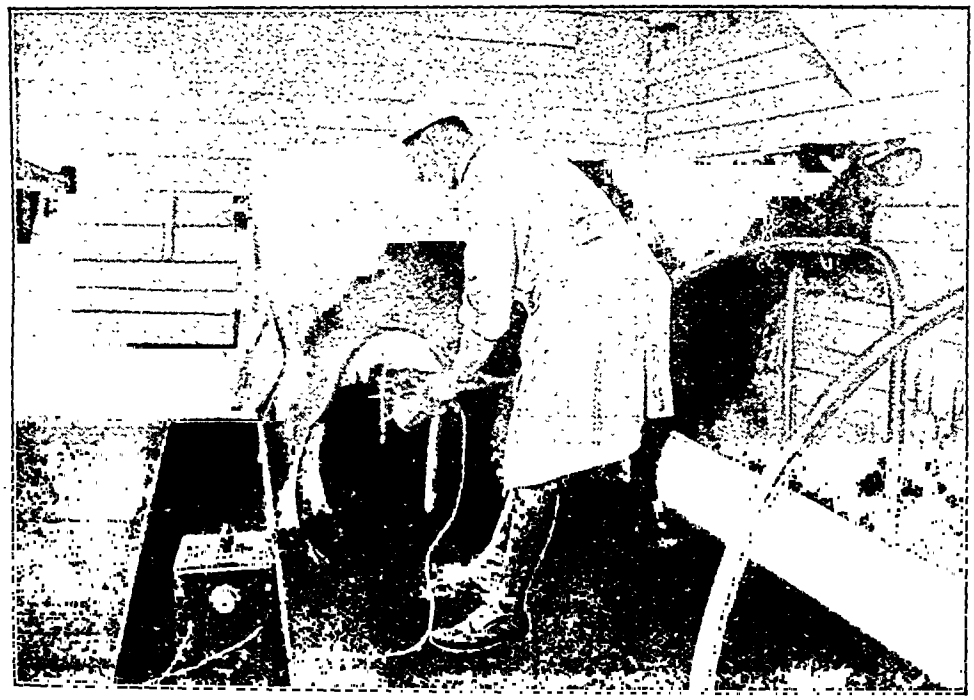
MICKLEFIELD IRRADIATED MILK



TREATING THE COW

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

(1) Average increase in height .605-in. (2) Average increase in weight 9.72 ozs. more than (1).
(2) " " " .610-in. (3) " " " 10.9 ozs. more than (1).
(3) " " " .744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every week-day in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S
PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

INSULIN 'A.B.'

EPHEDRINE B.D.H.

For Cold in the Head

B.D.H. Ephedrine preparations provide a ready means of giving prompt relief and comfort to patients suffering from nasal congestion and other unpleasant symptoms of the common cold.

To suit the convenience and idiosyncrasy of individual patients, Ephedrine may be prescribed in any of four forms.

Ephedrine B.D.H.
Elixir

A palatable preparation containing ¼ grain of the hydrochloride of Ephedrine B.D.H. per fluid drachm.

Ephedrine B.D.H.
Inhalant Compound

A solution of Ephedrine B.D.H. with camphor, menthol and oil of thyme in liquid paraffin.

Ephedrine B.D.H.
Nasal Jelly

Containing Ephedrine B.D.H. in pure petroleum jelly.

Ephedrine B.D.H.
Throat Spray

An aqueous solution of the hydrochloride of Ephedrine B.D.H.

Clinical sample of any of the above can be obtained on request from the makers

Fructole Calcium Lactate c Parathyroid

(Savory & Moore)

One of the recent additions to the well-known range of Savory & Moore's Fructoles.

The combination of Calcium Lactate with Parathyroid is recognised as desirable by the Profession in the various disorders dependent on deficiency of calcium.

Fructole Calcium Lactate c Parathyroid will be found of value where such impoverishment is diagnosed.

Supplied in 1 and 8 oz. bottles.

FRUCTOLES (Savory & Moore)

Fructoles made by Savory & Moore, Ltd., have for many years been regularly prescribed by the Medical Profession. These preparations covet a wide range of medicament in perfect solution, are palatable, and keep perfectly. They represent the highest standard of Pharmaceutical excellence.

Strict Analytical Control ensures purity of constituents, uniformity of product, supported by the guarantee of the makers.

Constant research and close contact with modern developments of medical science lead to new Fructoles designed to meet the demand of the modern practitioner.

Every Fructole may be prescribed with the greatest of confidence.

Samples and Literature of those more popularly prescribed are available for clinical test.

Vitamin Deficiency?

Put them on BEMAX

THE NATURAL VITAMIN TONIC FOOD

Bemax was prepared to provide a food rich in natural vitamins, which, added to the normal diet, would restore a balanced metabolism, and so create a condition in which remedial measures by the physician would be assured of the fullest success in all ailments due to deficiency of Vitamins A, B and E.

Laboratory reports on Bemax and clinical sample for personal trial will be sent to any medical man on receipt of his professional card.

THE BEMAX LABORATORIES, 23, UPPER MALL, LONDON, W.6.

In Capsules and in Solution

The Treatment of Urinary Tract Infections

For the prompt relief of pain, pyrexia, frequency of micturition and other unpleasant symptoms associated with diseases of the urinary system, 'Caprokol' therapy has proved remarkably effective.

'Caprokol' exerts a soothing effect upon the mucosa during the process of disinfection of the urinary tract.

Persistent treatment results, in the majority of instances, in complete sterilisation of the urinary system.

C-p/31

A pure carbohydrate food

that combats constipation, auto-intoxication & colitis

Lactose 73%, dextrin 25%—that is the proportion in which these carbohydrates are combined in this new food for changing the intestinal flora. Both are more slowly absorbed than other carbohydrates, and both are able to reach the colon in sufficient quantity to cause a luxuriant growth of protective flora. An acid reaction of the intestinal contents unfavourable to toxic organisms is thus produced—Lacto-Dextrin being highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon. In this pure carbohydrate food both lactose and dextrin are presented in a palatable and agreeable combination.

PSYLLA

. . . an accessory for use in conjunction with Lacto-Dextrin

Where bulk and lubrication of the intestinal tract is also required, the use of BATTLE CREEK Psylla (Plantago Psyllium) is invaluable as an accessory. The small brown seed when in contact with water swells into a soft gelatinous mass and acts most effectively both as an emollient and intestinal evacuant.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Gt. Tower St., London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

HORLICK'S MALTED MILK, a modified milk food, is full cream cows' milk combined with the nutritive extracts of malted barley and wheat, evaporated to dryness at a low temperature in vacuo by the special HORLICK process. *HORLICK'S MALTED MILK has proved of value in infant feeding, disease of the alimentary canal, myocardial disease, fevers, during pregnancy and lactation, and in all conditions where it is essential that the patient should be given a

palatable and agreeable diet, and one affording a maximum of nourishment with a minimum of digestive effort. *The characteristics of easy digestibility and absorption, and a high degree of assimilation, which have enabled HORLICK'S MALTED MILK to be confidently recommended by the Medical Profession for nearly fifty years, cannot be obtained from a blend of cereals and dried milk. *HORLICK'S MALTED MILK contains no free starch or cane sugar.

Reaching Laryngeal and Bronchial Inflammations

MANY laryngologists are advising the treatment of laryngeal, tracheal and bronchial inflammations by the direct route, nebulized spray solutions—in addition to the use of oral medication.

Mistol is ideally suited to this form of administration. When used in a nebulizer, it forms an exceedingly fine, almost invisible, vapour. This spray is unirritating to the upper respiratory passages and is drawn into the larynx and bronchi with each inspiration. In this way it reaches and exerts its therapeutic action upon the upper respiratory passages.

The ingredients of Mistol—menthol, camphor, eucalyptol, and chlorbutanol in high-grade liquid petrolatum—are endorsed by all leading rhino-laryngologists.

They relieve congestion and hyperemia in inflamed mucous membranes, diminish abnormal secretions, and aid in the return to normal conditions.

More and more physicians are finding in Mistol administered by means of a nebulizer a valuable ally to oral medication for laryngeal, tracheal, and bronchial inflammations.

HYPERPIESIS

HYPERPIESIS is described as "a malady in which blood pressure rises excessively, a malady having a course of its own and deserving the name of a disease."

A writer in *The Lancet* described cases of this condition, and ascribes its causation to toxic substances of the nature of which he is uncertain, but which he believes to be extrarenal in origin and to be distributed by the bloodstream.

It seems highly probable that these substances are the "pressor" substances, such as epinephrine, which are developed by putrefactive bacteria in the intestine. Assuming the truth of this likely hypothesis, the treatment in part should obviously consist in adequate intestinal disinfection

Certain compounds of the coal-tar series, having high germicidal value and little solubility in the alimentary tract, pre-eminently possess this disinfecting power and form the active constituents of Kerol, which may be given in a palatable form by means of keratin-coated capsules which ensure disinfection of the alimentary tract without deleterious effect.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Intestinal Disinfection

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alternative effects on the alimentary canal and tonic action upon the brain and nervous system generally.

In all the various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose: One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England 12/6 per pound.

Introduced and Prepared only by

The Medical Profession when prescribing "Liquor Carbonis Detergens"

SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

For Acute or Chronic Cases of Hyperacidity

For Gastric Duodenal or Pyloric Ulcers

M.232.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

Alasil

WHOOPING COUGH

Whooping Cough is a condition in which treatment with a suitable vaccine has proved remarkably successful. Some Practitioners, however, are deterred from using Vaccines, owing to fear of reactions, but this objection may be overcome by employing Detoxicated Whooping Cough Vaccine (Genatosan). In the preparation of this vaccine all the toxic elements of the germ are removed; as a result it is given to young children and infants without any harmful reaction and produces a high degree of immunity.

The following extract from a Practitioner's letter may prove of interest:—

"..... Some time ago, I resolved to try for the first time a vaccine in whooping cough and the results were so excellent, that I thought you would be interested to hear from me.

(*a*) Three children aged 3 years, 2 years and 8 months, were treated when the disease was about 10 days established; all were completely cured after the third injection—the mother described the effect to me as simply miraculous.

(*b*) Two aged 6 years and 3¼ years, who had relapses, were well after they had got the 2nd injection.

(*c*) An infant aged 8 months—the whoop disappeared after 1st injection. The cough was gone after 2nd injection, and the mother, who had tried everything and despaired of the child's life, was exceedingly grateful and assured me it was simply wonderful to see how the child had slept for the first time for days and was able to retain its food and rapidly put on weight. The Vaccine used was your Detoxicated Whooping Cough Vaccine. Speaking for myself, I can only describe the effects as magical, as the children were worn out and emaciated from coughing, vomiting, and loss of sleep."

Additional information regarding the above Vaccine will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

Peptonised Beef Jelly (BENGER)

and

Peptonised Chicken Jelly (BENGER)

These can be served either in their jelly state with a few biscuits, or dissolved in hot water in "beef-tea" form, making a valuable restorative readily assimilated by weak digestions.

Containing much of the flesh-forming elements of the meat in soluble form, these peptonised preparations are superior in effect to ordinary essences or extracts. Added to soups they considerably increase the nutrient value.

In hermetically sealed glass jars, 2/- and 3/- each.

NOTE.—Benger's Peptonised Beef Jelly and Chicken Jelly are entirely free from preservatives.

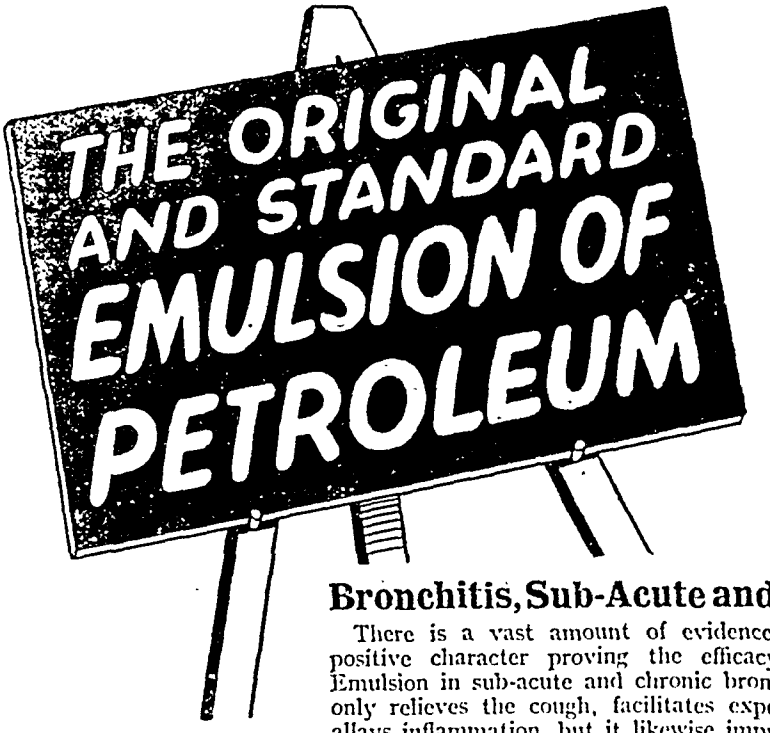
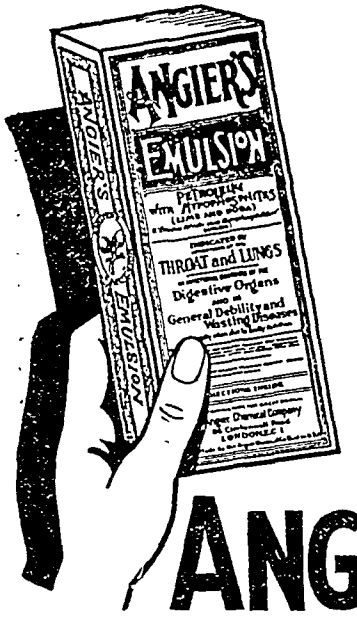
COW & GATE LTD. GUILDFORD, SURREY



Bronchitis, Sub-Acute and Chronic.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing "comforting" effects.



Pneumonia and Pleurisy.

The administration of Angier's Emulsion during and after Pneumonia and Pleurisy is strongly recommended by the best authorities for relieving the cough, pulmonary distress, and difficult expectoration. After the attack, when the patient's nutrition and vitality are at the lowest ebb, Angier's Emulsion is specially indicated because of its reinforcing influence upon the normal processes of digestion, assimilation and nutrition.

In Gastro-Intestinal Disorders

of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents. Fermentation is inhibited, irritation and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic material greatly facilitated.

STALACTITE VAULTING, A FORM OF ARCHITECTURAL DECORATION PIONEERED AND ERCUGHT TO PERFECTION BY THE ISLAMIC ARABIANS.—This form of decoration was used widely—in Sicily and Spain as well as in the East—by the Arabs, and so far as is known at present, by no others. It is employed to fill the vaults of mosques, to find spherical vaults to square surfaces and the outside galleries of minarets to their shaft, upon pendentives, corbelled masonry, heads of niches—wherever indeed it might serve to avoid plain angles and surfaces. Arab love of geometry seems to express itself everywhere in this form of decoration, which consists in intricate combinations of projections upon polygons, arcs, lines and curves, dropping, as it were, row beneath row, in a sort of honeycomb ending in "stalactites." The accompanying example is in stone.

BACK OF AN ASTROLOGICAL OR ASTRONOMICAL MIRROR OF THE THIRTEENTH CENTURY.—The scientific works of the Greeks were recovered and passed on to the Western world during the twelfth and thirteenth centuries, chiefly by Arabic-speaking scholars working in various Islamic centres of learning—though it was principally by way of Spain that the transmission of these, with Arabian additions and modifications, was made. Thus, Aristotle's works passed the Pyrenees and found their way to Paris and London. The Arabic translations were in their turn translated into Latin for the use of the West by scholars of many countries—among them the Englishmen, Adelard of Bath, the most renowned Arabic scholar of the twelfth century, and Michael Scot, who worked in Spain in the thirteenth. Roger Bacon, too, was steeped in Greek and Arabic learning. The polished metal mirror, the back of which, decorated with the Signs of the Zodiac, is here reproduced, may be called an astrological mirror.

OSTOMALT

is proving most useful as a tonic for adults convalescing from gastric or intestinal disorders—cases in which the routine type of tonic would not be tolerated.

OSTOMALT—consisting of pure malt extract of high diastatic value in combination with Ostelin vitamin D, vitamin A obtained by direct extraction from the cod's liver, and orange juice—contains vitamins A, B, C & D, in physiologically standardised amounts. Each dose can be relied upon for absolute uniformity.

In ½-lb. and 1-lb. jars, 2/6 and 4/-

Free Trials will be willingly sent on request to Glaxo Laboratories, 56, Osnaburgh Street, London, N.W.1.

Calcium is not absorbed in the absence of vitamin D

Injection of Colloidal Calcium is a recognised procedure, but it is found that much better effects are observed if vitamin D (Ostelin) is given simultaneously, since absorption of calcium is thus promoted.

Colloidal Calcium with Ostelin is thus an ideal combination. The therapeutic effect is rapid, and injections can be given daily if desired and continued for a week or more.

Colloidal Calcium with Ostelin is *indicated in tuberculosis*, especially in incipient cases, when it is a most valuable adjunct to routine treatment: in fracture cases, when it promotes callus formation: in *chilblains*, in which it is almost specific: and in urticaria, eczema, and other skin diseases associated with hypocalcæmia.

Colloidal Calcium

with Ostelin vitamin D

For subcutaneous injection. In bottles of six 1c.c. ampoules, 5/- per box: or in 1-oz. bottles, 10/- per bottle. (Subject to usual professional discount.)

Schorstein Memorial Lecture
ON
RADIUM IN THE SERVICE OF SURGERY

DELIVERED AT THE LONDON HOSPITAL, OCTOBER, 1930

BY
H. S. SOUTTAR, D.M., M.Ch., F.R.C.S.
SURGEON TO THE HOSPITAL

When in 1898 Becquerel and Curie discovered radium they opened up a field of research which has revolutionized physical science, changed our conception of the structure of the universe, and brought nearer to realization the hope of finding a cure for cancer. These are great achievements, yet the more the subject is studied the more does it appear that we have as yet only glimpsed a new world of discovery, and that no one can tell what treasures may lie beyond.

THE PHYSICS OF RADIUM

It was the study of radium which led Rutherford to conceive of the atom, not as an inert and indivisible particle, but as a minute solar system with a nucleus around which electrons move, each in its own special orbit, with inconceivable velocity. Each electron carries the same minute negative charge of electricity, and under certain conditions it may actually be driven from its orbit and fly away into space, in which event the atom develops the peculiar property known as ionization, which serves as the basis of chemical action. The change may be only temporary, for the electron may be replaced from some other source, and the atom so return to its normal neutrality; or the ionized atom may combine with other atoms to form the molecule of some new substance.

But it is the nucleus rather than its satellites which interests us at the moment. The nucleus is built up compactly of electrons and of protons, each of the latter carrying a positive charge equal to the negative charge of an electron. Of the structure of the nucleus little is known except that within it four protons and two electrons are often combined together as a unit of peculiar stability, which is known as an alpha particle. In the simplest atom of all, the hydrogen atom, the nucleus is a single proton round which one electron circulates with a speed comparable to that of light. Next in order comes the helium atom, whose nucleus is an alpha particle around which circulate two electrons. Beyond these we have the atoms of all the other elements, with nuclei of increasing complexity, until at last we reach the atom of uranium, whose nucleus contains 238 protons and 146 electrons, while around it circulate 92 electrons. Most of these atoms are entirely stable, and remain unchanged through all time; but certain of them present the curious property of decay, and slowly change into less complex forms. The change is nuclear and, in contrast to the transitory phenomenon of ionization, it is permanent. It is effected by the violent ejection from the nucleus of either an alpha particle or an electron, which is then known as a beta particle. The ejection is so violent that the alpha particle may start with a velocity of 10,000 miles a second, and the beta particle with a velocity which may approach that of light; but in addition the ejection is accompanied by a terrific output of energy in the form of a stream of waves of very high frequency, known as gamma rays. So high is the frequency that of even the longest of these waves 5,000 would be required to span a single wave of light, while the hardest rays may be one hundred times as short at this.

These elements decay from one to the other in certain definite series, of which by far the most important is the uranium series, of which radium is a member. Radium is a metal, but each ejected alpha particle becomes the atom of a gas, radon, which again, by a similar process, decays into radium A, B, and C, finally reaching stability as lead. Radium itself decays so slowly that 1,750 years have elapsed before one-half of it is gone, but radon has a half-value period of only 3.85 days, while radium A, B, and C last for only a few minutes each. You will see, then, that in radium we have a source of prodigious energy, giving out a constant stream of alpha, beta, and gamma rays. For our purposes we require only the last, and we are fortunate in possessing in the heavy metals screens by means of which the alpha and beta rays can be cut off. If we surround a small quantity of radium with a screen of platinum 0.6 mm. in thickness, practically the whole of the alpha and beta radiation will be cut off, but only 25 per cent. of the gamma rays. A platinum tube with a wall 0.6 mm. in thickness and filled with radium thus furnishes us with a source of almost pure gamma rays, and resembles a minute *x*-ray tube. There is, however, the difference that the gamma rays are far harder than any *x* rays, and have a far higher penetrating power, while their enormous energy is well shown by the fact that for their production by ordinary physical means we should require a potential of over three million volts.

Radon

In some ways radon is even more remarkable than the radium from which it emanates. It is a heavy, inert gas with no known chemical affinities; it decays with such rapidity that at the end of nine days only one-fifth remains. It may be pumped off from a solution of radium and packed in containers, carrying with it what is for all practical purposes the entire radio-active power of radium itself. Its vast energy is contained in so minute a volume that the emanation of one gram of radium for a whole month constitutes only 0.6 c.mm. of evanescent gas; yet this minute bubble contains within it 1,000 millicuries of radiant energy, and for the moment the whole potency of a gram of radium element. The effect of the two substances must be different, because their rates of decay are so different, but, so far as the production of energy is concerned, compensation is easy. The total decay of

100 millicuries of radon, a process which takes a month to complete, is accompanied by the discharge of almost exactly as much energy as that given off by 100 mg. of radium in 5.5 days.

RADIUM AND THE CELL

Unfortunately our knowledge of the weapon we are using contrasts in a striking manner with our ignorance of the tumours we are attacking. Our knowledge of the life-history of the cancer cell is very meagre, and almost the only known fact which is useful for our present purpose is that it is constantly dividing. It would appear, however, that this constant division renders malignant tumours susceptible to the action of radium and enables us to use it for their destruction.

Gamma rays have little or no effect upon the normal life of a cell; the movements of protoplasm remain unaltered and ciliary movement is unaffected. The contractility of muscle fibres, the conductivity of nerves, and cellular metabolism in general, are not perceptibly affected by an excess of gamma rays; there is even evidence that their presence is necessary for normal metabolism. On the other hand, gamma rays markedly affect the reproduction of the cell, and cells are especially vulnerable at the moment of karyokinesis when cellular division is about to take place; even if the cell is not destroyed mitosis is affected and abnormal forms are produced. It appears that the chromatin is especially fragile at this moment, being rapidly absorbed, with the resulting death of the cell. This is best seen in the lymphoid cells of lymphatic glands, where fragmentation and absorption of the chromatin may be completed in a few hours; in the genital cells of the ovary the same process may occupy three or four days.

Irradiation of Gonads and Skin

A brilliant light was thrown on the action of radium upon dividing cells by Regaud, who studied the effect of irradiation on the testicle. Working on rats he showed that properly controlled irradiation has a strictly selective action on the different cells, and thereby produces a remarkable series of results. In the seminiferous tubules the cells are arranged in a peculiar manner. Deep in the wall, in contact with the basement membrane, are situated the spermatogones; internal to these are at least four generations of descendant spermatocytes; and lining the lumen of the tube are the spermatozoa themselves, descended from the spermatogones after six or more generations. All these cells are supported in a jelly-like syncytium, from which they derive their nourishment; and this syncytium is itself maintained by the cells of Sertoli lying between the spermatogones close to the basement membrane.

Of all these cells the spermatogones are by far the most sensitive to irradiation, and it is easy to destroy them completely without apparent injury to any other structures. If this is accomplished a curious train of events follows. Spermatozoa are produced in a normal manner for about four weeks, but at the end of that time they disappear and the animal is completely and permanently sterile. The source of supply has been cut off, and the apparent latent period is simply the period of development of the accumulated stock of embryonic spermatozoa which have remained unaffected by the radiation. If, however, some of the spermatogones have escaped, they may be able to resume their function completely. The sterility is only temporary, and after a time the animal can reproduce in a normal manner. In spite of their proximity, the cells of Sertoli and the syncytium which they control are entirely unaffected by an irradiation which can annihilate all the spermatogones.

A similar selective action is seen in irradiation of the skin. The deep, constantly dividing cells of the stratum germinativum, from which the whole skin is derived, are more sensitive than the superficial cells, and it is upon them that the brunt of the injury falls. But several days will elapse before any change appears on the surface, and it may be a fortnight before sloughing of the skin shows the extent of the destruction.

The selective action of gamma rays upon dividing cells, and the apparent latent period of their effect, are so important and characteristic that I have thought it well to refer to them in some detail. They are fundamental in all that concerns the clinical applications of radium, and whatever their ultimate meaning may be they furnish us with a practical basis for our work.

Irradiation of Other Tissues

It seems highly probable that the gamma rays destroy the cancer cell at the moment of its division; that the constant division of the cells is what renders them vulnerable; and that the escape of the normal tissue cells is due to their comparative quiescence. The minute mechanism of the process is obscure. The chromatin condenses and then fragments, to be absorbed by the cytoplasm, which then itself dissolves, but this is the furthest limit to which we can follow the process. The primary histological effect is upon the chromatin, and the action must be a chemical one induced by ionization of the protoplasmic molecule or of some part of it by the gamma rays. So far as we know the action is strictly intracellular, and no indication has ever been discovered of any toxic substance which can pass from cell to cell.

It would appear, then, that sensitivity to irradiation is a specific property of the individual cell, and this is borne out by the very great variations shown by the cells of different tissues. In general, the epithelial tissues, the generative cells, and lymphoid tissue are radio-sensitive, whilst the connective tissues, muscle, and nerve are highly insensitive. Tumours of any sort in which rapid division of the cells occurs tend to be sensitive, while those of slow growth, such as fibromas and lipomas, show no reaction at all to therapeutic doses. When a sensitive tumour has been exposed to a therapeutic dose of gamma rays, destruction of its constitutent cells starts within a few hours, and is probably almost complete in a very few days. The sole object of continued radiation is to ensure that no cells escape through their period of division having been missed. Some days elapse, however, before the effect becomes clinically apparent, though softening of the tumour may perhaps be detected within twenty-four hours. The actual disappearance of the tumour depends on its absorption by the connective tissues, which, as we have indicated, are only affected in a very minor degree. To this gradual absorption is due the apparent latent period, and not to any actual delay in the action of the radium.

It would, however, be entirely incorrect to imagine that the connective tissues are unaffected by irradiation. They are very definitely affected, but in a manner entirely different from that of a tumour and of epithelial structures. Following the application of a single large dose, or of repeated doses, changes occur, perhaps not apparent at the time, but permanent in their effect. The resistance of the tissues to injury is greatly reduced, and this fragility may come to light only after a very long period. This is most strikingly seen in the bones, which show no immediate change, but may, years later, fail to respond normally to injury or infection. Thus the removal of a tooth years after irradiation of the tongue may lead to extensive necrosis of the jaw, a matter of great importance in treatment.

It will be seen that the clinical removal of a tumour by irradiation is a highly complex process in which destruction of the tumour cell and its absorption by the connective tissues both play a part. The possibility of cure rests on the hypothesis that the difference in sensitivity of the two tissues is so great that we can destroy the one without unduly injuring the other.

DOSAGE

It will be seen at once that the problem of dosage is of vital importance, for on the one hand too small a dose will fail to destroy the cancer cells, while too large a dose will probably injure our allies, the cells of the connective tissue. As a rough guide it is generally taken that the energy irradiated during the decay of 1 millicurie of radon, or, what is physically the same thing, the energy irradiated from 1 mg. of radium in 5.5 days, is capable of destroying all cancer cells within a sphere having a radius of 5 mm. As, however, the energy absorbed by a given cell is inversely proportional to the square of its distance from the source of radiation, it is obvious that though the cells at the surface of this little sphere receive just a lethal dose, the irradiation near the centre is altogether excessive. We are at once faced with the difficult problem of obtaining a uniform radiation.

One method is to concentrate a large quantity of radium, at least four grams, in a bomb, and to keep this at such a distance that the effect of the law of the inverse square is reduced. A still more uniform effect is obtained if the bomb is kept in constant progressive movement, or if it is moved at intervals so that the radiation enters the tumour from different directions. But the method is wasteful in the extreme, as only a minute percentage of the energy of the radium is absorbed. The effective treatment of a single case might easily monopolize for a fortnight a bomb costing £50,000.

More effective, though less dramatic, is the use of radium needles on a moulded support. The needles which we use are platinum tubes with walls 0.6 mm. in thickness, containing radium sulphate, so packed that each centimetre of the tube contains 1 mg. of radium element. These are supported on a sheet of spongy rubber or of wax moulded to fit the region, and from 1 to 2 cm. thick. The needles are so arranged that a nearly uniform dose is delivered throughout the underlying region, and if the tumour is not too large or too deeply situated a sufficient degree of uniformity can be obtained. The method gives very good results in cutaneous tumours of the face and eyelids, and it has been largely used in carcinomas of the glands of the neck, though to be effective here it demands a large quantity of radium.

Far more efficient and economical is the introduction of platinum needles or seeds containing radium or radon into the tissues, for here radiation is absorbed in every direction and not only on one side. The arrangement of the needles or seeds so as to get the best result demands considerable experience and a high degree of skill; but here I can refer to only one of the factors that must be taken into consideration—namely, the effect of crossfire.

Crossfire

How considerable this effect may be can be shown by a simple example. I have stated that 1 millicurie of radon can destroy all the carcinoma cells in a sphere of growth 1 cm. in diameter, and it might appear at first sight that a tumour 8 cm. in diameter would require 512 millicuries, since its volume is 512 times that of the small sphere. As a matter of fact if the radon is uniformly distributed throughout the sphere the total amount required to produce a lethal dose at its centre is only 21.3 millicuries, while if double this amount—namely, 42.6 millicuries—is uniformly distributed throughout the sphere every particle of growth in this large volume will be destroyed. In actual practice one would probably insert in the case of such a large tumour something like 100 millicuries, a considerable portion of which would be distributed around the tumour and not in the tumour itself. By such means an enormous volume of tissue can be subjected to radiation of a uniformity limited only by anatomical landmarks and the dexterity of the surgeon, a volume so large as to include not only the tumour itself, but the whole surrounding lymphatic area as far as it can be reasonably followed. One has in fact introduced into the tissues a kind of diffuse bomb, and uniformity has been gained economically by a wide distribution of foci so small as to be individually weak, and yet so many as to be collectively powerful, owing to the great effect of crossfire.

Introduction of such large numbers of seeds and their accurate placing can only be accomplished conveniently by some special appliance, and I have therefore devised an instrument for the purpose. It consists of a fine cannula 15 cm. in length, with a revolving magazine at the proximal end which carries ten seeds. The introducer is held in the left hand and the magazine is rotated by the thumb, the seed being pushed down through the cannula and delivered into the tissues by means of a plunger held in the right hand. The magazine is detachable, and a spare one is provided for an assistant to fill while the instrument is in use. The seeds are by this means introduced with great rapidity, with a high degree of accuracy, and with practically no trauma.

THE USE OF RADIUM IN SURGERY

For many years the surgical use of radium was almost limited to the cervix uteri and the skin, but it is now becoming evident that our previous failures in dealing with cancer in other regions were largely due to defects in technique. Cancer of the cervix and rodent ulcers of the skin respond to radium with extreme readiness, and methods which are entirely successful in these cases are useless to the general surgeon. The introduction of needles and of seeds is a great advance, and personally I feel that the local cure of cancer of almost every form is only a matter of time. This is far from saying that we shall be able to cure cancers that have spread widely from their site of origin, though in some cases even wide lymphatic spread has been overcome.

Causes of Failure

As Regaud has pointed out, failure may be due to one of several causes: (1) The area involved may be too large for uniform irradiation. (2) The tumour may not be radio-sensitive, so that though it at first diminishes in size enough cells survive to reproduce the tumour. (3) The surrounding normal tissue may be as sensitive as the tumour, as commonly happens in the intestinal tract. (4) Secondary deposits may be present.

Cancers of the skin and of the mucous linings of the cutaneous orifices are all very sensitive to radium, and in cases of limited extent 90 per cent. are capable of cure. Even in extensive and inoperable cases local cure may be expected in 40 per cent.; but in these cases secondary deposits may appear in the glands, and here from their extent they are less easily treated; indeed, it is possible that it is best to treat the glands by direct surgery. The histological type of the tumour is closely related to its radio-sensitivity. Thus, of epitheliomas of the skin, the baso-cellular type (rodent ulcer) responds most readily, and the squamous type is more resistant, while intermediate forms show a variable reaction.

The enormous importance of secondary spread is well seen in a comparison between early cases of cancer in

the lip and in the tongue. In both regions the local cure of the disease by the introduction of radium is almost a foregone conclusion, whereas, however, in cancer of the lip, from which secondaries only arise at a late stage, a permanent cure of an early case is so certain that the glands may be ignored; in cancer of the tongue, invasion of the glands is the rule, and their treatment presents a problem of the greatest difficulty. Glandular organs such as the breast respond as a rule satisfactorily to the insertion of radium in the form of seeds or needles, but in this region diffusion is rapid, so that one can never be certain that a local cure will not be followed by secondary deposits at a distance.

Sarcomas react in a very variable manner. Lympho-sarcomas and sarcomas of a myeloid type disappear rapidly, but both are liable to produce secondary deposits. Myelomas react well and do not produce secondaries, but spindle-celled sarcomas show an indifferent reaction. Other malignant tumours of mixed structure are on the whole resistant, but in a variable degree.

APPLICATION IN SPECIAL REGIONS

The principles of radium therapy can be more readily understood in their application to special regions, and I therefore propose to describe briefly the methods by which seeds can be applied in three characteristic regions—namely, in the breast, the tongue, and the rectum.

The Breast

The situation of the breast renders it specially convenient for the introduction of seeds, and enables one readily to observe the results. The introduction of the seeds can be carried out through half a dozen small punctures; with the instrument I have described the process can be carried out with great rapidity and precision. As the punctures heal immediately there is no possibility of sepsis, and the patient is saved from the discomfort caused by the threads and the removal of needles.

The distribution of the seeds will, of course, depend on the situation and dimensions of the tumour and on the existence of secondary deposits in the axillary glands. In all cases, however, the region just beyond the growing edge of the tumour is infiltrated with long columns of seeds radiating from one puncture, perhaps five rows with five seeds in each row.

Above these, further columns of seeds are introduced through another puncture, the columns transverse to those of the first group, so as to obtain as uniform a distribution as possible. The first layer of seeds lies in the pectoral fascia, and the second in the substance of the tumour or in the adjacent breast. It appears to be unnecessary to introduce seeds on a more superficial plane, and it is inadvisable to do so in view of the danger of destroying the overlying skin. The cannula is now introduced through a puncture in the axilla and passed up beneath the pectoral muscles parallel to the axillary vein, but at a distance of 1 inch below it in order to avoid any risk to the brachial plexus. A long line of seven or eight seeds is here deposited, and then another at a lower level and in the substance of the pectoralis major through the same puncture. Rows of seeds are thereafter planted along the axillary border of the pectoralis minor and upon the surface of the serratus magnus just behind it, and finally separate seeds are introduced one into each of the intercostal spaces and two into the sheath of the rectus.

This general arrangement may have to be modified in dealing with very large tumours or where there are large masses of secondary glands, but in any case an endeavour must be made to subject the tumour and the whole lymphatic system of the breast to as uniform an irradiation as possible.

At the end of a week quite a definite change can be noted in the consistency of the tumour. Its outlines become indefinite and it becomes softer, while a slight diffuse oedema can be felt in the whole region. At the end of three weeks shrinkage of the tumour will be obvious, but if it is of some size even three months may elapse before it disappears or is replaced by a soft mass of fibrous tissue with none of the characteristics of a carcinoma. It is, of course, of the utmost importance that these cases should be closely followed, and that one should not assume from the normal appearance of the breast that all danger has disappeared, but I must say that so far the results I have obtained have far exceeded my hopes. A small but important point of practice is that the skin should be covered every night with cold cream. This will greatly diminish the skin reaction and obviate any serious dermatitis, except in cases in which the skin is actually involved by the tumour.

The Tongue

There can be no question that in the tongue radium is the method of choice for the cure of a carcinoma, and in this region the convenience of seeds cannot be questioned. Here, again, the object is to infiltrate the growing edge of the tumour with a uniform barrier of seeds, and the only difficulty lies in the precise definition of the extent of the tumour. The number of seeds introduced will, of course, vary with the nature of the case, but as a rule from ten to sixteen 1.5 millicurie seeds will be required. These should be screened with platinum, since it is important that the mucous membrane of the tongue and palate, and the bone of the jaw, should be protected from the action of beta rays.

The introduction of the seeds is a very simple matter, though an anaesthetic is almost essential. Usually the cannula is introduced through the normal mucous membrane and the seeds are deposited in short but regular rows. If the growth is situated far back, the cannula is guided by a finger placed upon the ulcerated surface, when it is quite easy to judge of its depth in the soft substance of the tongue. In some cases, and especially in growths extending on to the floor of the mouth, the cannula may be introduced with advantage from the neck beneath the jaw. The whole object is to secure a uniform irradiation of the growing edge of the tumour, and one should avoid the temptation to concentrate seeds in the tumour itself.

Here, again, the course of events is very characteristic. In forty-eight hours it will be noted that the induration is less, while in a week it will have almost disappeared and the growth will be definitely smaller. At the end of two weeks the growth is replaced by a flat ulcer, covered by a smooth white layer of creamy lymph with a curiously sharp margin where it meets normal mucous membrane. Rapid shrinkage now occurs and the epithelium grows in from the margins, so that at the end of three or four weeks the surface is healed and only a puckered scar remains. The total deformity is trivial, and contrasts remarkably with anything that can be obtained by operation.

Unfortunately dramatic success in curing the local growth in the tongue is only too often accompanied by disheartening failure to check recurrences in the cervical glands. It still remains an open question whether they should be removed by block dissection or whether they should be treated by irradiation. The method I am myself adopting is to infiltrate the whole region with seeds, and there is no doubt that in almost every case the enlarged glands have rapidly diminished in size. It is, however, far too soon to speak of results, but at the moment I feel more inclined to attribute failures to defects in technique than to unsoundness in the method.

The Rectum

The rectum is a region peculiarly adapted to the use of seeds, whether the growth is within reach of the anus or can only be reached from the abdomen. In the former case the growth itself and the whole of the pelvic tissues round it can be easily infiltrated with seeds from two punctures in the perineum on either side of the midline. With the patient in the lithotomy position the needle of the introducer is inserted to one side of the tip of the coccyx and fifteen platinum seeds of 2 millicuries each are introduced in long columns so as to be deposited as uniformly as possible on that side, and the procedure is then repeated on the opposite side. In this way, with a posterior growth, a substantial barrier of seeds can be constructed in the hollow of the sacrum behind the rectum in order to irradiate both the base of the growth and the rectal glands. The infiltration of a growth on the anterior wall is a little more difficult on account of its greater mobility. If the growth is situated on a higher level it must be exposed by laparotomy and the seeds introduced across the peritoneal cavity. The introduction of the seeds is perfectly simple, and as asepsis can be strictly observed it is not accompanied by any special risk; but as in this region the growth has usually encircled the bowel and produced obstruction, a permanent colostomy is almost essential.

Carcinoma of the rectum is very sensitive to radium, and a localized tumour may disappear with great rapidity, while even in advanced cases the insertion of radium may make it possible to remove a growth previously inoperable. The only difficulty is that the rectal mucosa is itself highly sensitive to radiation, and great caution in dosage is therefore necessary, since an excessive dose may produce a severe proctitis. Even where a successful result has been obtained it is probably safer, if the patient will consent, to excise the rectum from the perineum three months later wherever this is possible, for in the present state of our knowledge it is impossible to be certain that some portion of the growth has not escaped destruction.

CONCLUSION

There can be no doubt that in radium we have a weapon of extraordinary power in the treatment of cancer, but we are still far from knowing all its possibilities or from being able to direct its energies to the best advantage. May I suggest tentatively a few directions in which progress may be made?

On the physical side we must aim at obtaining perfect uniformity of radiation so that the whole area involved will receive equal treatment. The obvious method would be to store a vast amount of radium in a single bomb, but to my mind such a method is too wasteful to be practicable. It seems to me that the method I have suggested of uniform infiltration is more likely to lead to practical results, since here the whole of the energy of the radium is utilized instead of a minute fraction. I am endeavouring to devise methods by which still smaller seeds can be produced, so that the whole volume may be literally peppered with minute foci. But here one is limited by the fact that a certain thickness of metal must be retained to form a screen, however small the content of the seed.

A tumour is affected solely by the portion of radiation it absorbs. One of the uses of rays of high penetrating power is to reach tumours at a depth without injury to the overlying tissues. If by some means we could increase the opacity of the tumour we should proportionately increase the efficacy of our radiation, and if at the same time we could render the skin transparent, we should have solved one of the most difficult problems in radiology. On the biochemical side it does not seem impossible that some method might be devised for sensitizing the tissue of a tumour, and I would point out that this is more likely to be effected by stimulating its growth than by reducing its vitality. There is something fascinating in the idea of stimulating the cells of a growth to more rapid division in order that they may meet with more certain destruction.

How subtle is the problem you will see from an experiment originated by Zwaardemaker, but repeated by Professor Dixon of Cambridge, who described it to me. You are aware that a frog's heart perfused with Ringer's solution can be kept alive and beating normally for several days. The solution contains a minute trace of potassium, an element with a small but definite radioactivity. If this trace of potassium is removed, the heart at once flags and soon ceases to beat. If, however, before it has stopped, a few milligrams of radium are brought into its neighbourhood it immediately resumes its normal pulsation. It would seem, indeed, that gamma rays are essential to our very existence, facilitating in some subtle way the chemical changes upon which our life depends.

On the clinical side I feel certain that much might be done to protect the normal tissues upon which, as I have shown you, we largely depend for success. A very short experience of radium will show, for example, the immense importance of protecting the skin, and I do not think that it is sufficiently recognized how great a protection it is to keep the skin soaking in ointment. Subjected to this treatment the skin will hardly react, even if enormous doses are introduced into the tissues.

Far more difficult is the problem of dissemination. Irradiation of the whole body would probably lead to the death of the patient, so that perhaps it is fortunate that it is at present impracticable. I am told that irradiation sufficiently general for our purpose may be found in unlimited quantity in even the closest nebulae, but so far no means of access to this source has been provided.

But there is one line of progress open to us all. There is no doubt whatever that the cure of cancer would be vastly simplified by early diagnosis and early treatment. Surely it is not too much to hope that as people realize that cancer can be cured in its early stages by radium, they will no longer hesitate from the dread of an operation to consult their doctor. Much will be done by investigators in their laboratories and by surgeons in hospitals, but it is the general practitioner, in the ordinary course of his work, who must teach the public that the cure of cancer is waiting if only they will ask for it in good time.

THE ROLE OF THE GENERAL PRACTITIONER IN ANTE-NATAL WORK*

BY

W. H. F. OXLEY, M.R.C.S., L.R.C.P.

MEMBER OF THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The Departmental Committee on Maternal Mortality and Morbidity, after careful consideration of the subject for nearly two years, reported that a large number of maternal deaths could be prevented if all women had efficient ante-natal care, and it considered that it should, wherever practicable, be undertaken by the person who would be called in for any abnormality of labour—namely, in most cases, the general practitioner.[1] This recommendation is bearing early fruit, for the scheme adopted by the Cumberland County Council, which was published in the *British Medical Journal* of October 18th, 1930 (p. 649), provides that a general practitioner shall

* A British Medical Association Lecture delivered to the Winchester Division.

examine ante-natally every case attended by a midwife, either at a clinic or at his own surgery. I understand that in Hampshire the clinics are now to be staffed by general practitioners, although I believe that provision is not yet made for the examination to take place in the doctor's own surgery. This is rather a pity, as one of the most important parts of ante-natal care is the establishing of perfect confidence between doctor and patient; and where can this be done better than in the consulting room? Publicly provided ante-natal clinics have so far failed to produce any manifest effect upon maternal mortality, largely owing to want of co-operation with the general practitioner, and the latter must now prove what he can do in bringing about the desired effect.

THE PRACTICAL WORKING OF A CLINIC

Very important factors conducing to the success of ante-natal care are: (*a*) the patient must be made to realize early that a deep interest is being taken in her welfare; (*b*) she must obey in every detail the instructions given to her; (*c*) these instructions must be reduced to their utmost simplicity. Without the full co-operation of the patient success will be impossible. A special leaflet of instructions is given to every mother at the hospital with which I am connected, and acts as a reminder of the advice given to her by the midwife in charge. It would be improved by the provision of a space on the back on which to enter the next appointment. If the patient receives the impression of protection, there will be no difficulty in getting her to attend, but if she misses an appointment she should be visited and the reason discovered for her absence.

The clinics are to be staffed by general practitioners and midwives, and it should be realized from the first that their duties are not antagonistic but complementary. There must be no divided responsibility; there must be a definite understanding of the work of each. It should be remembered that practically all midwives have gone through a training and passed an examination in their work, and have paid what is for most of them a fairly considerable fee. They are rightly jealous of the right to practise midwifery conferred upon them thirty years ago, and they are sensitive lest, now that a doctor is to be associated with them in the ante-natal care of all their booked cases, there may be a tendency to reduce them to the lower position of maternity nurse, without any separate responsibility at all. I am sure that none of us want that; the midwife is more fitted by nature to exercise the patience and the gentle care which are so essential to the well-being of every case, and has proved her value as a necessary member of the obstetric team. The well-trained midwife knows that she has to do with normal cases only, and she is able to do this and also to recognize the early signs of abnormality. The better she is trained the oftener will she call the doctor, and she should be encouraged to take over as much of the routine work as possible. It is the half-trained woman who exceeds her duties. It will tend to the smooth working of the clinic if the midwife who has booked the case is given the duty of examining and taking full particulars of her cases before bringing them before the doctor. She should fill up a record card. She should present her case to the doctor, who will find out whether she considers it a normal case or not, and will go over it with her, explaining any abnormality found, pointing out things she may have missed, and giving her definite instructions as to any treatment required. In most cases it will be her duty to carry this out, and the more responsibility is left to her the greater will her skill and interest in the work become. She should be able to test the urine, to recognize malpresentations, and, as pregnancy approaches its term, to determine the size of the foetal head in relation to the pelvis, and even to forecast the probable course of labour with some degree of accuracy. There is a danger of giving the midwife a false sense of security by telling her that there is "nothing wrong" with a case. Such statements should be always qualified with the words "at present," letting her clearly understand that the responsibility is still upon her to look out for abnormalities. The doctor will soon get to know those midwives he can trust, and will get a good deal of interest out of the work of training those whose knowledge is insufficient.

Record cards should be filled up in duplicate for every case—one for the clinic and one for the midwife. Entries should be made on both at every visit of the patient, and the midwife *must* take her card to the confinement. Nothing is so annoying to the doctor when he is called for in an abnormality than ignorance of the ante-natal findings. The card we have used for many years measures 5 by 8 inches, small enough to go into the midwifery bag or pocket, and yet large enough for all necessary entries. The midwife fills up the front, and the doctor puts any observations he wishes to make on the back in red ink. A separate chart and record combined is kept for the confinement, and a brief note of the result of the confinement is made on the record card for permanent reference.

THE PRINCIPLES OF ANTE-NATAL CARE

So much has been written lately upon ante-natal care that there is no need for me to go over the ground, but I would like to draw attention to the chapter on it in the interim report of the Departmental Committee on Maternal Mortality and Morbidity, and to the appendix on "Ante-natal clinics: their conduct and scope." Each doctor working on the staff should get a copy. Before discussing the common abnormalities met with during ante-natal care, I should like to stress the necessity of looking after the general health of the mother. In an analysis I recently made of the work of the East End Maternity Hospital in the last five years, it was found that six out of the seven mothers who died were seriously ill with some intercurrent affection before labour commenced, and the deduction was fairly drawn that any material reduction in the already low maternal death rate of the hospital was largely dependent upon an improvement in the general health of the mother. This is again an argument for the employment of the general practitioner in this work, for the most vigilant ante-natal clinic is bound to lose sight of some patients who fall ill during pregnancy; the expectant mother goes to her family doctor, who, if connected with the clinic, will have to consider the influence of the disease upon her pregnancy, and will be in a better position to obtain the help required.

Heart disease is very frequently met with in association with pregnancy. Ninety-six cases were picked out by the midwife in charge of our ante-natal department out of the 10,376 cases attended during the last five years. In the majority the disease was suspected by the midwife on account of the history of scarlet or rheumatic fever. No symptoms were complained of, compensation was good, and, provided the obstetric conditions were normal, these women passed through pregnancy and labour without requiring special care. A note of the condition was always made on the record card which accompanies the patient, so that she should not be allowed a long or difficult second stage. In others the extra strain of pregnancy had made manifest some latent heart trouble, the symptoms complained of being chiefly breathlessness, anxiety, and sleeplessness. They required rest for a certain time each day; but as most of our patients are working-class women with home duties, such an order could not be obeyed at home, and they were persuaded

to come into hospital. The moderate cases respond remarkably well to treatment; only six were so ill as to require induction of labour before term. Irregularity of the heart is a sign which the midwife is told to report to the doctor at once. A practical point to be remembered is that in those mothers who are too ill to feed their babies belladonna plasters must not be applied by the midwife to the breasts, on account of the paralysing action of atropine upon the vagus, with consequent quickening of the heart's action.[2]

Influenza, pneumonia, and other acute diseases are not seen in the ordinary ante-natal clinic, but under the new regime the general practitioner will be expected to do his best to guide the patients through such illnesses, with an eye to the future labour. One woman we had lately did not let us know she was ill. She went to her own doctor, who prescribed but did not visit her, and in some way she was not missed when she failed to appear at the ante-natal department. She died after an easy labour, and post-mortem examination revealed malignant endocarditis, a disease which is frequently mistaken for influenza. This death was probably due to the divided responsibility, which we hope to avoid in future.

Purulent vaginitis and cervicitis is frequently met with (74 cases out of 10,000) and may be gonorrhoeal, although in nearly every one it is an exacerbation of a simple cervicitis due to the hyperaemia of the parts during pregnancy. In any case it should be treated, and we have found douches useless for the purpose. The cervical canal should be thoroughly swabbed with a saturated solution of picric acid in spirit. If a great deal of softened tissue is present a Volkmann's spoon may be used to scrape it away; provided the internal os is not entered there is no danger of bringing on premature labour. This little operation can be done in a private house if a suitable light can be provided, and in many cases an anaesthetic is not required. The best speculum to use is a fairly long Sims, the Auvard as usually made not being long enough to reach into the posterior fornix in pregnancy, together with the very useful anterior speculum designed by Remington Hobbs. The cervix should be drawn down with tissue forceps, as varicose veins, which bleed if wounded with a vulsellum forceps, are often present on the cervix during pregnancy, and so obscure the view of the external os. Pain is not caused if the cervix is not pulled sideways, and if the well-lubricated specula are not pressed upon the sensitive vestibule. Having treated the cervix, slowly withdraw the specula, swabbing the vagina as the rugae are smoothed out in front of them. The patient should lie down for an hour afterwards. One of the midwives attached to the service can be taught to hold the specula while the doctor does the swabbing, and during the following week she should give a daily simple douche.

Pyelonephritis is another common condition requiring treatment during pregnancy, and should always be suspected when a patient from the sixth month onwards has a rise of temperature with a pain in the right side. Pus and *B. coli communis* are found in the urine, and this condition is frequently missed by the midwife. The patient needs rest in bed, copious barley water, and aperients. The treatment we have found most successful is the changing of the reaction of the urine. It is usually acid, and a mixture containing a large dose of sodium citrate is given; at the end of a week or so the urine is again turned acid by the exhibition of hexamine with sodium acid phosphate.

Syphilis should be suspected if there is a history of previous premature labours or stillbirths, and a Wassermann reaction test taken. Ten years ago this disease was extremely [illegible]

about the twenty-fourth or twenty-sixth week of pregnancy it will be successful in nearly every case in procuring a healthy full-time child. This is one of the few conditions occurring in the course of ante-natal care where the help of an expert is necessary.

Dental treatment should be arranged for. There is no evidence that this is likely to bring about miscarriage.

There is hardly need to mention constipation except to say that while it may be merely a discomfort in ordinary life, in pregnancy it may be a real danger; it is present in all severe cases of toxaemia. We find the most satisfactory treatment is by phenolphthalein and medical paraffin.

Special Abnormalities of Pregnancy

Cases of toxaemia with hyperemesis are not very common, but are extremely serious. If they do not soon clear up under treatment, and in any case if the liver becomes affected, immediate emptying of the uterus is indicated. It is not worth while running risks, as the chances of a live baby are remote.

Albuminuria.—The possibility of the almost complete eradication of eclampsia by means of systematic examination of the urine during pregnancy, and drastic eliminative treatment, is now well recognized, but the treatment of it in the patient's home is most unsatisfactory, and so the case will be removed from the care of the general practitioner unless the authorities can be persuaded to allow him to take his part in the staffing of maternity hospitals. In hospital the treatment by starvation, purgation, and washing out the body by fluid is almost always successful in avoiding eclampsia. The patients drink freely of barley water, made palatable by a little lemon flavouring. They are given barley sugar in order to avoid acidosis, and after a day or two, as the amount of urine increases, and the albumin gets less, are put on to vegetable soups, fruit, spaghetti and tomatoes, and a variety of milk puddings. Too much milk does not appear to be good for them. On account of the danger of permanent damage to the kidneys, or death of the foetus, cases which do not clear up with two weeks of this treatment are induced, even though it may mean the birth of a non-viable child. The chance of the patient having a live child if she has had a serious condition of toxaemia before the twenty-eighth week is too remote to make it worth the risk, quite apart from the possibility of eclampsia. The number of cases admitted to hospital were 104 out of 10,000.

Posterior positions of the vertex should be diagnosed by the midwife and brought to the attention of the doctor. These positions are the most troublesome cases with which the midwife or doctor has to deal.

The sequence of early rupture of membranes, slow dilatation of the cervix, exhaustion of the mother, death of the foetus, extraction by forceps, trauma, and death from sepsis, is all too common. Efforts should therefore be made to do rotation. Buist's binder has been used for this purpose at the hospital, but it is difficult to be dogmatic as to its effect, as a large number of cases diagnosed as posterior before the head is engaged rotate spontaneously, and when the head has engaged it has no effect. One is inclined to think, however, that if the head is late in engaging, either through disproportion or want of flexion, it does influence rotation. That is to say, it is effective in just those cases which are likely to be difficult, and should therefore be tried in all. We have certainly had fewer dangerous cases since it has been used systematically. It requires careful fixing by the doctor and daily adjusting by the midwife.

Breech presentations should also be diagnosed by the

maternity hospitals and found that 30 per cent. were still-born and 9 per cent. died before the fourteenth day. On account of these dangers, external cephalic version has been practised at the hospital for many years, and is usually performed at or about the thirty-fourth week of pregnancy. Later than this it is difficult and frequently impossible in primigravidae. In twin pregnancy it is usually impossible, and extension of the legs is another common cause of failure. In a few cases where repeated efforts have been made, there has been slight haemorrhage on the following day, and in others the umbilical cord has been much twisted. If an experienced doctor and midwife were to be present at every breech delivery the foetal death rate could, of course, be very much reduced, and the necessity for turning be avoided, but under present circumstances there is no doubt that the lives of many children will be saved thereby. Although the Central Midwives Board rules permit a midwife to attend breech cases in primiparae, we always direct her to call a doctor on these occasions.

CONTRACTED PELVIS

The diagnosis of contracted pelvis is simple, and can be made at any period during pregnancy, but there is no need to do so until about the thirty-fourth week, as treatment, whether by induction or Caesarean section, would not be taken until after then. The midwife should be instructed to suspect contracted pelvis if the mother is less than five feet in height. She should also take the external measurements of the pelvis—interspinous, intercristal, posterior interspinous, and external conjugate—and should call the doctor's attention to any deviation from the normal, and especially to all cases in which the external conjugate diameter measures 7 inches or less. It is as well for the doctor to check the midwife's results from time to time. In the early days of ante-natal care treatment was frequently based upon the result of these findings, but now the pendulum is swinging the other way, and the measurements are frequently said to be of no value. Both views are wrong. As a matter of fact, careful measurements do give some idea both as to the type of contraction and as to its degree. The mere anatomical fact of contraction being present is, however, not sufficient; we want to know much more than that. First, is the contraction of such a degree as to preclude absolutely the passage through the pelvis of a living child? Secondly, will the contraction interfere with the birth of a normal full-term child? Thirdly, will it interfere with the birth of the particular child which has to come through that individual pelvis? The third question is the important one. We have found that in at least 80 per cent. of cases in which there is a definite contraction, the normal course of labour is unaffected thereby. To diagnose and treat correctly the other 20 per cent. is where the difficulty comes in. What signs, other than the measurements, can be used as a guide; in other words, what influence has contraction of the pelvis to an obstetric degree upon the signs of pregnancy? In most cases nothing unusual will be found until the thirty-sixth week. At that time the upper pole of the foetus reaches the costal margin, and, after that, growth can take place only forwards, downwards, or sideways. If there is resistance to the usual downward growth a prominent abdomen or obliquity of the uterus will result. The former sign is the more common in multiparae, the latter in primiparae. Owing to the looseness of the abdominal muscles in a multipara, the head frequently does not engage in the pelvis until labour begins. In them the best guide to the probable course of labour is the previous history, although this is not infallible, owing to the increasing size of the child and weakness of the uterus with the increasing number of pregnancies. In a primipara, however, a head floating free above the brim at the end of the thirty-sixth week is an almost certain sign of contraction of the pelvis to an obstetric degree. The midwife should be taught to recognize these signs and to bring them to the notice of the doctor. In some cases, especially in flat pelves, the difficulty of engagement will cause the foetus to rotate on its long axis and become a breech, and in all breech presentations discovered during pregnancy this should be borne in mind. In many cases in which the head is found above the brim, it can be made to enter by pushing it downwards and backwards. In some cases, however, it is impossible to do this, the child's head bulging the lower part of the abdomen, and "overriding" the symphysis, and in these it is clear that a sufficient degree of disproportion already exists to interfere with the normal course of labour. Midwives will often inform the doctor that the head "pushes in," but it is well to beware of this statement, as in many cases in which they say it has done so the largest diameter of the head is still above the brim. Disregarding the few cases in which non-engagement is due to the presence of a tumour or of placenta praevia, it will be caused by occipito-posterior position or disproportion in size between head and pelvis, and a vaginal examination will be necessary. At this examination the diagonal conjugate will be measured, and, by sweeping the tip of the forefinger round the brim an idea as to the roominess at the sides can be obtained. If in a relaxed patient the promontory cannot be felt, it may be taken that the pelvis is normal. If the diagonal diameter measures 4 inches, induction at the thirty-sixth week will be necessary if the child is of normal size, and if less than 4 inches, Caesarean section will probably be the correct treatment.

In cases of slight contraction, with a diagonal conjugate of four and a quarter to four and a half inches, the question as to whether induction will be necessary at all, and, if it is, the decision as to the right time for performing it, is of the greatest difficulty. The answer depends upon so many factors, such as degree of overlapping, amount of room at the sides, condition of the mother, etc., that we are frequently finding that "experience is fallacious and judgement difficult." In these doubtful cases the best course is to prepare for induction, and to decide finally with the patient under deep anaesthesia. With the patient in the lithotomy position two fingers may be placed in the vagina, and the head pushed down upon them by the external hand, and a more accurate estimation of the relative size of head and pelvis thus be made. In a pelvis of the small round variety, the slightest degree of overlapping indicates immediate induction, but in a large flat pelvis with plenty of room at the sides slight overlapping will not prove an insuperable obstacle to the birth of a live child.

The operation of induction can be performed in a private house provided the two great difficulties—namely, (*a*) the obtaining of aseptic conditions, and (*b*) a good light—can be overcome. Krause's method has proved most successful with us. Large-sized bougies, about No. 13, are used; they are soaked for twenty-four hours in 1 in 1,000 perchloride of mercury and boiled for a minute immediately before use. The midwife can show the cervix in the way before described, and there is usually no difficulty in inserting the bougies at or after the thirty-sixth week, provided they are allowed time in stretching the internal os. In multiparae, and even in primiparae, who are not nervous, an anaesthetic is not necessary, if the help of a second midwife can be obtained.

It is a remarkable fact that in the last five years, during which 10,376 cases have been attended at the hospital, only one Caesarean section has been done, every other case of contracted pelvis having been treated by induction at or about the thirty-sixth week, or by the applica-

tion of forceps. It seems, however, that many obstetric surgeons, imbued with what may be called the "furor operativus," make the mere diagnosis of contracted pelvis a reason for the performance of this operation, apart altogether from other considerations. If cases were carefully considered on the lines given above, there is very little doubt that many unnecessary Caesarean sections would be avoided.

If I have gone rather minutely into detail, my excuse is that the more I think over the problem of maternal mortality the more convinced I become that it is only by close attention to every detail, and by co-operation between all the members of the obstetric team, and especially between general practitioners and midwives, that we shall make any real impression upon the number of women who are every year dying preventable deaths.

THE ACCESSORY LOBE OF THE AZYGOS VEIN

BY
H. P. NELSON, M.B., F.R.C.S.
DEMONSTRATOR OF ANATOMY, ST. BARTHOLOMEW'S HOSPITAL
AND
GEORGE SIMON, M.B., D.M.R.E.
CHIEF ASSISTANT, X-RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL

The accessory pulmonary lobe which occurs at the apex of the right lung was first observed by the anatomist in 1778, but its radiographic appearances were not identified until 1923. Since radiographic examination has become the most fruitful method of investigation of the lungs it seems desirable to present a detailed account of the appearances of this infrequent pulmonary variation.

Anatomy

The accessory lobe of the azygos vein is an additional pulmonary lobe occurring at the right apex, and separated from the remainder of the apex by a fissure containing the vena azygos major. The vena azygos major pursues its usual course behind the oesophagus just to the right of the midline until it reaches the level of the sixth thoracic vertebra, when, instead of arching forwards over the root of the lung, it turns in a lateral direction, dipping into the upper lobe. There, after passing forwards and inclining medially, it terminates in the superior vena cava. The vein, contained in a complete pleural septum, separates the dome of the pleura into two compartments, with the result that an accessory lobe is split off from the medial side of the right upper lobe. This septum consists of both visceral and parietal layers of the pleura, and is so disposed that its outer surface is convex and the lower free margin, which contains between its layers the vena azygos, is arched. It thus forms a kind of meso-azygos (Fig. 1).

The anatomical descriptions of this abnormality are fairly unanimous, and the following account is based on the papers by Geddes, Holtby, and Stibbe; the last reviews all the cases that have appeared in the literature up to 1918. The position of the fissure, and in consequence the size of the accessory lobe, depend on the degree of lateral deviation of the vein. The fissure may split the outer surface of the upper lobe at a point 2 inches below the apex, and the fold will then lie more or less horizontal, the accessory lobe forming the greater part of the apex of the lung. On the other hand, the fissure may merely split off a small tongue-shaped lobe from the mediastinal surface of the lung. The average lies between these two extremes, the fissure usually descending from the apex of the lung. The level of termination of the azygos vein with the vena cava superior is higher than normal, usually at the junction of the two innominate veins, and meets the lateral instead of the posterior surface of the vena cava. The depth of the fissure varies, but usually approximates to that of a primary lung fissure. In some of the described cases the vena azygos was resting on the eparterial bronchus, while in others there was as much as an inch of lung tissue between the deepest part of the fissure and the bronchus. The bronchus supplying the lobe comes from the eparterial: in three cases it has been described as having an N-shape, first ascending into the lung on the outer side of the fissure and then down under the azygos vein to ascend into the accessory lobe.

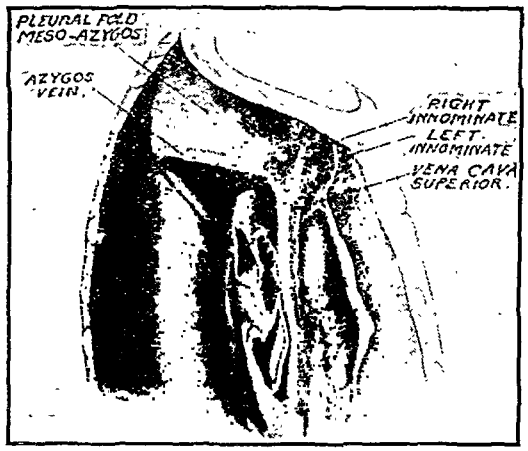

FIG. 1 (after Stibbe).—A case that has been dissected to show the mediastinal surface of the right pleural cavity after removal of the lung and accessory lobe. The pleural fold is shown with the vena azygos major running in its free margin.

In the *development* of this condition there are two variable factors: the growing lung buds and the growing cardinal veins. The posterior cardinal vein arches forwards across the coelom to join the duct of Cuvier, and it brings with it a fold of primitive pleural membrane, which divides the apex of the pleural-coelomic cavity into a medial and lateral compartment. The lung bud grows upwards and outwards, passing usually lateral to the vein, and with the descent of the heart the vein is drawn downwards and inwards and the medial apex obliterated. Now if there is a slight alteration in the position of either of these factors—a lung bud not lateral enough or the vein too lateral—the pleural fold would impinge against the lung and split off a medial process, which will expand upwards as the accessory lobe. Other accessory lobes, less common than the one here described, have occurred above and below the root of the lung. These other lobes have unfortunately been called "azygos lobes," and it is to distinguish it from these that the lobe we are concerned with has been called "the accessory lobe of the azygos vein." The fissure which separates these "azygos lobes" is lined only with visceral pleura, and is thus similar to a primary lung fissure, but the fissure which separates off the lobe of the azygos vein is lined by both visceral and parietal pleura.

Radiography

In 1923 Wessler and Jackes first drew attention to a falciform shadow near the right apex occasionally seen in antero-posterior radiograms of the chest. In 1928 Wessler and Bentick observed this shadow in two patients in whom later the opportunity occurred at post-mortem to compare the anatomy of the lungs with the radiographic appearance. Both of these cases had an accessory lobe of the azygos vein, and they were thus able to prove beyond all doubt the cause of this shadow.

CASE I

E. B., a woman aged 35, was sent for an *x*-ray examination of the chest in order to exclude active tuberculous disease. She had a slight cough, but no abnormal physical signs. The *x*-ray film shows no evidence of disease of the lungs. In the antero-posterior film there is a fine white line which descends from the medial side of the right apex, with a convexity to the right, to end at the level of the second costal cartilage. The distance from the line to the side of the vertebral column

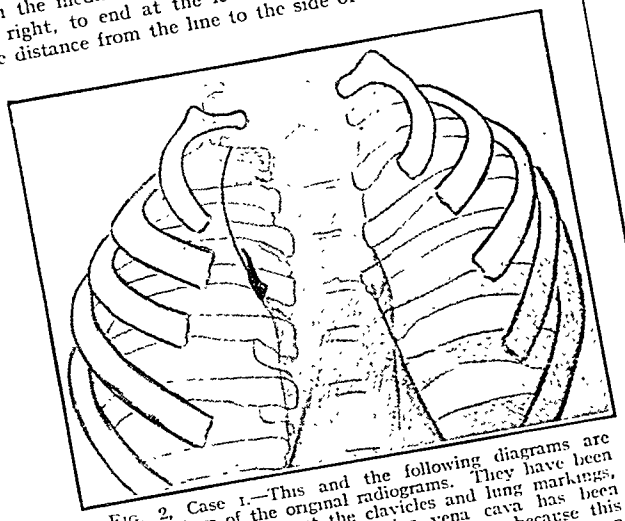

FIG. 2, Case I.—This and the following diagrams are exact tracings of the original radiograms. They have been simplified by leaving out the clavicles and lung markings, while the shadow of the superior vena cava has been accentuated. The radiograms are not shown because this abnormal shadow is not sufficiently noticeable to be seen in the radiograms after reduction in size and reproduction in print

is 25 mm. at its widest part. The line terminates by running into the side of a horn-shaped shadow, which has an opacity equal to that of the aortic arch. The broad, lower end of this shadow merges into that of the superior vena cava at the level of the upper part of the second intercostal space, while the thin upper end turns medially to lie 1 mm. to the inner side of the line at its lower end. The apex of the lung medial to the line is slightly opaque (Fig. 2).

CASE II

P. B., a boy aged 15, was admitted to hospital with acute rheumatic pericarditis. An *x*-ray examination of the

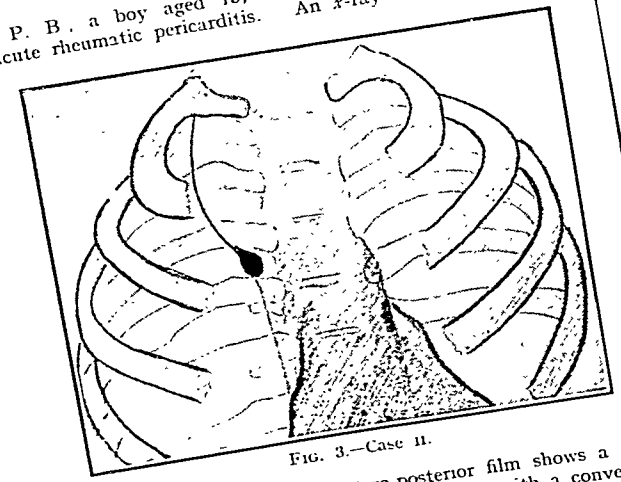

FIG. 3.—Case II.

chest was made, and the antero-posterior film shows a fine white line descending from the right apex, with a convexity to the right, to end at the level of the second intercostal space. The distance of the hair line to the vertebral column is 33 mm. The line terminates by running into the apex of a pear-shaped shadow, the broad end of which is continuous with the shadow of the superior vena cava. The great density of this pear-shaped shadow makes it stand out very clearly. The apex medial to the line is clear.

CASE III

D. P., a girl, aged 9, suffering from tuberculous glands in the neck, was sent for *x*-ray examination for the presence of enlarged mediastinal glands. The *x*-ray film shows no evidence of enlarged glands. The antero-posterior film shows a fine white line which descends from the medial side of the right apex, with a convexity to the right, to end at the upper border of the first costal cartilage. The distance of the line from the vertebral column was 15 mm. The line terminates at

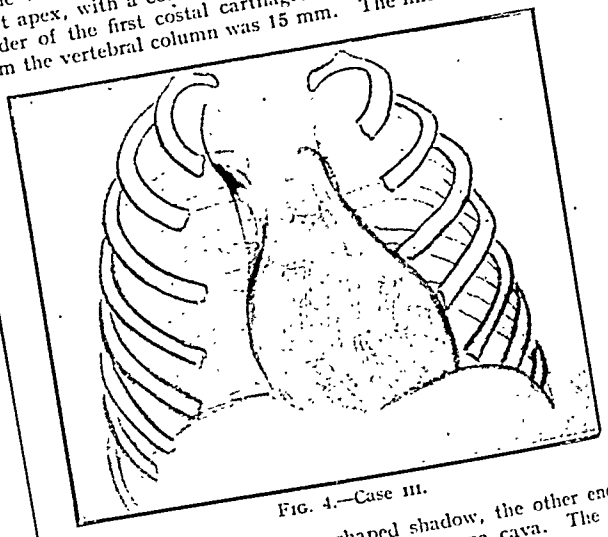

FIG. 4.—Case III.

the upper end of an oblong-shaped shadow, the other end of which is continuous with the superior vena cava. The lung medial to the line is slightly opaque.

The lateral film shows a white line (considerably wider than that seen in the antero-posterior film) running upwards and forwards from the back of the fourth thoracic vertebra and ending in the first intercostal space on the same plane as the posterior surface of the trachea. This line is 2 inches long.

CASE IV

F. S., a boy aged 8, suffering from recurrent attacks of bronchitis, was seen at a tuberculosis clinic and sent for *x*-ray examination. The antero-posterior film shows a fine white line which descends from a point at the lateral side of the right apex, with a large convexity to the right, to end at the level of the second intercostal space. The line is 40 mm. from the vertebral column at its widest part. The shadow at the lower end of the line is quite different from that of the three

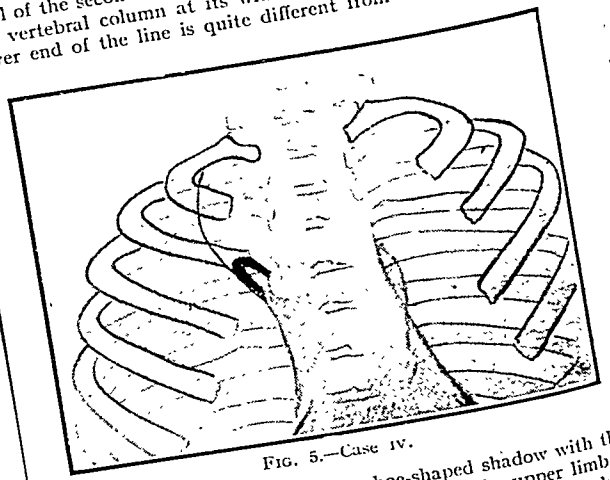

FIG. 5.—Case IV.

preceding cases. There is a horseshoe-shaped shadow with the concavity pointing downwards and inwards, the upper limb is on the level of the second costal cartilage, and the lower limb in the second intercostal space. The line can be seen to run into the outer side of the lower limb of the horseshoe-shadow. This shadow is only slightly denser than that of the superior vena cava.

The normal lung fissures can only be seen in radiograms of the chest if the incidence of the rays is in line with the

plane of the fissure. Thus the septum which separates the accessory lobe only casts a shadow for that part of its course which is in line with the rays, when it appears as a linear shadow. The position of the line will vary with the width of the accessory lobe. The topography of the vena azygos, which can be seen at the lower end on the medial side of the linear shadow, exhibits considerable variation. This variation depends on the depth of the fissure. In Case IV the whole of the arch can be seen projecting well out into the lung field; in Case II the vein is lying close against the side of the mediastinum, and the arch is coming almost directly forwards, which accounts for its great density as compared with Case IV. In the other two cases the vein is intermediate in position and density of shadow between that of Cases II and IV. Rawling states that the normal vena azygos opens into the superior vena cava at the level of the lower part of the second right intercostal space: the level of termination is seen in these cases to be higher than in the normal, Cases II and III being opposite the first interspace and Cases I and IV opposite the second costal cartilage.

Pathology

The only pathological condition that has been found in this lobe is due to obstruction of its bronchus by the vena azygos. Müller described the case of a boy, aged 18, who had myeloid leukaemia. The radiogram of the chest showed an abnormal shadow projecting laterally from the mediastinum above the hilum of the right lung, which was thought to be due to enlarged lymphatic glands. The boy died of the leukaemia, and the post-mortem revealed that the shadow seen in the radiogram was due to an accessory lobe of the azygos vein, which showed important pathological changes. The bronchus leading to the lobe was narrowed to a slit at its point of contact with the vein, while beyond this the bronchus opened up into a series of bronchiectatic sacculi filled with mucus. Muller's case suggests that the opacity observed in the lobe in two of our cases might be due to a partial obstruction of the bronchus. Bentick and Wessler observed the shadow of an accessory lobe in a patient who had a carcinoma of the right lower lobe. A pleural effusion developed, and at the same time the hair line became progressively wider, probably owing to an interlobar effusion.

Apart from these two cases there is no record of any pathological state associated with this congenital abnormality.

Frequency

In 1916 Stibbe reviewed the twenty-three cases that had been reported in the literature since 1778, when Wrisberg first described the condition. Nineteen of these cases were reported in anatomical journals between 1866 and 1899.

More accurate statistics can now be obtained from the radiological departments of large chest hospitals. Mather, from the Royal Chest Hospital, Liverpool, reports four cases in 3,000 consecutive radiograms of the chest; while Sparks (personal communication), at the City of London Hospital, Victoria Park, has had six cases in 6,000 consecutive radiograms of the chest. Thus the incidence of this abnormality is approximately 1 per 1,000 of the population. The condition is also much more frequent in males than females.

THE KNEE-JERK AND ITS VARIATION

AN INDICATION FOR SYMPATHETIC RAMISECTION OR TRUNK SECTION

BY

N. D. ROYLE, M.D., CH.M., F.C.S.A.

SYDNEY

There are a number of diseases in which the deep reflexes, such as the knee-jerk, are increased in excitability and have a prolonged relaxation time, with few or no oscillations when coming to rest after elicitation. This occurs in Raynaud's disease, some cases of Buerger's disease, Hirschsprung's disease, and in certain other vasospastic conditions. Dr. Harry Harris has found similar phenomena exhibited by patients suffering from certain types of renal pain. These diseases are due to abnormal activity of the sympathetic nervous system, as is distinctly indicated by the manner in which each condition responds to operations on this system. The presence of these abnormal reflex phenomena may be used as an indication for operation, because they disappear, or are modified, after the interruption of sympathetic influence.

How to Test the Knee-jerk

The knee-jerk is a myotatic reflex, and depends on the stretching of the quadriceps for its elicitation. This is usually accomplished by flexing the knee when the patient is reclining, or sitting upright in a chair. The first position does not adequately stretch the quadriceps to induce tone. The second position allows the effect described by Magnus and de Kleijn to come into play—that is, an increase in tone in all extensor groups of muscles caused by contraction of the extensor muscles of the head, thus exaggerating the amount of tone present in the tested muscles.

Reinforcements of the Knee-jerk

Various methods of reinforcing the knee-jerk are used, such as pressing the hands together and making the patient look at the ceiling, but these reinforcements interfere with the exact state of the knee-jerk, in that they call into action a cortical contribution to tone.

The Ideal Position for Testing a Knee-jerk

To test a knee-jerk the patient should be in a reclining position. The head and back should be supported, so that the contraction of extending muscles of the neck is not evoked. The knee should be bent and allowed to swing freely over the edge of the bed or couch. In this position the quadriceps muscle is stretched, and this stretching induces whatever tone the quadriceps is capable of exhibiting.

Phases in the Knee-jerk

When the patellar tendon is tapped there is a phasic response in which the knee extends, and a subsequent variable phase. If tone is exaggerated the leg will stay

in the extended position momentarily and return relatively slowly to the position of flexion. If the position of flexion is assumed without oscillations of the leg, tone is hypernormal. If oscillations are of wide amplitude and continue for a time, the quadriceps muscle is hypertonic. In spastic paraplegia, for example, if the failure of the hamstrings to relax does not prevent a definite extension, the reflex is delayed; the return to the starting position of flexion is slow, and the oscillations are absent. Finally, the leg hangs in a partially extended position, maintained by the tone of the quadriceps muscle (Fig. 1).

Even in locomotor ataxia the leg does not hang perpendicularly, but in slight extension, though not as extended as in the normal leg. After ramisection the leg hangs perpendicularly (Fig. 2) unless there is contracture of the quadriceps muscle. If contracture is present, the leg will take up an extended posture, and the reduction of tone after operation will then be indicated by the short period of relaxation.

FIG. 1 FIG. 2

FIG. 1.—Showing extension of normal leg on stretching the quadriceps muscle.

FIG. 2.—Showing position of left leg after sympathetic ramisection contrasted with the normal right leg.

Tone as an Indication for Operation

In Raynaud's disease, Hirschsprung's disease, and Buerger's disease the character of reflex activity, as shown in the knee-jerks, may be used as an indication for operation. In every case of Raynaud's disease and of Hirschsprung's disease that I have personally examined hypertonus has been present. It may be present in Buerger's disease; it is almost invariably present in epilepsy.

In the normal person hypertonia is rarely present. To ascertain this I examined the knee-jerks of fifty medical students. In every instance except three the knee-jerk was normal in relaxation time and in oscillation. Of these three, two students, both mile runners, exhibited hypertonus, and in the other, a victim of poliomyelitis, the phasic response was absent, and the leg hung perpendicularly from the knee.

CONVALESCENT SERUM IN PROPHYLAXIS OF MEASLES*

BY

D. N. NABARRO, M.D., F.R.C.P.

DIRECTOR, PATHOLOGICAL DEPARTMENT, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

AND

A. G. SIGNY, M.R.C.S.

ASSISTANT PATHOLOGIST TO THE HOSPITAL

Serum or whole blood taken from patients recovering from a disease has often been used in treatment empirically, and with varying results. Thus it has been employed in poliomyelitis, encephalitis lethargica, measles, and scarlet fever.

Historical

Nicolle and Conseil in 1916 were the first to succeed in protecting with convalescent serum a child who had been exposed to measles. Since then many observers have published their results, and all agree that the value of the serum, if properly used, is very great. Degkwitz in Munich and Debré in Paris control clinics where the serum is collected, prepared, and issued to all who require it, and they have thus treated many thousands of children with very striking results. Debré was the first to point out that the results are even more satisfactory if the serum is used to produce a mild attack rather than complete protection. It is obvious that as soon as a causal organism is definitely established and an animal serum prepared, the human serum will fall into disuse owing to the difficulties inherent in the procuring of sufficient supplies. At present the animal serums available are those of Tunnicliff, Degkwitz, and Ferry and Fisher. All these are prepared from a green streptococcus which, it is held though not generally accepted, is the causal agent of the disease. In a comparative survey of these serums with convalescent serum, Gunn of the Metropolitan Asylums Board showed that:

Ferry and Fisher's serum protected	0 per cent.
Degkwitz serum protected	40 ,,
Tunnicliff's serum protected	43 ,,
Convalescent human serum protected	95.7 ,,

These figures are similar to those obtained by several workers, and show conclusively that, at present, the human serum is by far the most reliable.

Collection and Preparation of Serum

Since measles occurs mainly in children, it is with the greatest difficulty that we are able to obtain a sufficiency of blood from a donor. We have been fortunate in the co-operation of Dr. Massingham of the London Fever Hospital, where many adult cases of measles are treated, and he has kindly bled these cases for us. Each patient should be carefully examined before bleeding, and the greatest care taken to exclude anyone with the possibility of another infection. Particular notice is taken of any syphilitic or tuberculous taint, and no patient is bled except after a normal uncomplicated measles. Between the seventh and fourteenth days after defervescence 200 to 300 c.cm. of blood is collected aseptically into sterile oxalate solution, this allowing a yield of 50 per cent. of serum after precipitating the oxalate with calcium chloride. Sterility tests and a Wassermann reaction are done on every serum and, if these are satisfactory, 0.5 per cent. phenol is added and the serum is then pooled with several other serums so as to obtain as far as possible a final product of uniform potency. Before use the serum is filtered through a Seitz bacterial filter and a final sterility test done.

Effects of Administration

No ill effects have ever followed the use of a carefully prepared serum, and any unsatisfactory results can nearly always be traced to insufficient care in the preparation. It is sometimes said that the above technique does not preclude the administration of a tuberculous serum; in

* Read in the Section of Medicine at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

fact it has been pointed out that since children after measles are particularly susceptible to tuberculous infections, which would not be obvious when they are bled in early convalescence, it must be an unwise and even dangerous practice to bleed measles patients. These assertions are readily countered by the following facts. Tuberculosis in children after measles is common probably only because of their debilitated condition, and is not due to any specific predisposition. Nevertheless, we have taken our bloods almost entirely from adults, who do not develop tuberculosis as do children. Further, the precautions taken in phenolizing and passing through a bacterial filter render the serum sterile, and these should satisfy even the most sceptical. Professor Kraus of Vienna has examined by animal inoculation many specimens of convalescent measles serum which had not been treated with the double precautions mentioned above, and he has never yet thereby produced a tuberculous lesion in a guinea-pig. As the serum is of human origin anaphylaxis or serum reactions do not occur. The serum can be used so as to give different results, and these depend on the stage of incubation at which the injection is made. Copeman's ideas upon the inoculation period of measles are as follows:

In order to achieve complete protection the serum should be injected before the fifth or sixth day of incubation. This is called "sero-prevention," and results in a passive immunity which lasts roughly a month. From the sixth to the ninth day the serum does not protect fully, but allows only a very mild attack of measles to ensue. To this the term "sero-attenuation" is applied. There is a moderate attack, with the establishment of active immunity. After the ninth day we cannot hope for any benefit from serum. Injection on the tenth day produces Debré's phenomenon, a local blanching at the site of injection. Epidemiologically the attenuated attack is the best result that can be obtained, as it confers on the individual a permanent active immunity, whereas in the case of a patient who has been completely protected he has only a temporary passive immunity lasting two to four weeks. From the practical point of view it is clear that in institutional work one must always aim at complete protection, whereas in private practice, where it is only the individual who has to be considered, the best result is a mild or aborted attack. Of course, where a desperately ill child has been exposed to measles we must at all costs prevent the attack, and it is advisable to use a slightly larger dose, and to administer it as early as possible in the incubation period. The attenuated attack is indeed an extremely mild affair. Some cases exhibit a small bout of pyrexia to 100° F. for a day or two about the fourteenth day of incubation; others vary from a few measly spots over the trunk (apyrexial) to a typical attack of measles with coryza and bronchitis, which has all subsided in from twenty-four to forty-eight hours. We have never seen Koplik's spots in any of these measles cases after convalescent serum has been given. A very common feature is a prolonged incubation period—in some cases even as long as twenty-six days—followed by a mild measles. There is no doubt that from a hospital administrative point of view this can be rather disturbing, as it holds a ward in quarantine for over three weeks. If, however, all new admissions to the ward are given serum, this in no way hinders the work of the ward, which may continue its normal routine.

Dosage

Originally we used 3 c.cm. for children up to 3 years and 5 c.cm. for children over 3. This has never been strictly adhered to, as we increase the dose for big children and for adults, and also if the incubation is well advanced. We have now increased our doses to 5 and 7 c.cm., and believe that this is a more adequate and satisfactory dosage. All the injections are made intramuscularly into the buttock. Serum has been tried in treatment of severe measles without success, because the antibody content is not sufficiently high and enormous doses would be required to have any effect. For the same reason the serum is of no value for the blanching of a rash, although it is sufficiently strong to prevent the appearance of the rash in an area if injected before the rash appears generally (Debré's phenomenon). Whole blood may be used instead of serum, and in this case the blood of a convalescent is injected intramuscularly into the recipient, the dose being double the serum dose.

Results

At the Paris Clinic, where an enormous number of children have been treated, Debré reports 80 per cent. protection. Gunn reports 95.7 per cent. complete protection, and of his 5 failures 3 were injected on the first day and two on the eighth day. The two latter doses were, of course, given too late for complete protection, and the other three cases were so mild as to be hardly recognizable as measles. Our own series now amounts to 586 cases, of which 461 were injected by us at the Children's Hospital following ward infections, and 125 were cases from practitioners in various parts of the country following home or hospital infections. In the hospital series there were 14 failures, or 3 per cent., and the outside cases 7 failures, or 5.6 per cent. As we have already noted, the "failures" in both series include several injected after the fifth day, and are almost all extremely mild cases.

Analysis of Twenty-one "Failures"

Serum Injected	Aborted	Mild	Normal	Severe	Total
Before fifth day of incubation	3	3	4	0	10
Sixth to tenth day	1	9	1	0	11*
Totals	4	12	5	0	21

* It should be noted that these 11 cases should really be omitted, as they are examples of late inoculations where a mild measles is to be expected. Of the 10 before the fifth day 6 were so mild as hardly to be recognized as measles.

Controls

It is a matter of some difficulty at the moment to obtain satisfactory controls. It is almost impossible to say how many children in an infected ward would develop measles if not inoculated, but it is very common for several patients to contract measles within a fortnight. We can show several such wards, quite typical and representative of many, in which within fifteen to sixteen days four or five children of varying ages have contracted measles, and in some the infection has then recurred so often as to necessitate closing the ward. Furthermore, we should really know how many patients have previously had measles, but this again we think can be assumed to be, in the same hospital over a prolonged period, a constant figure. Even a previous attack, of course, does not necessarily confer an immunity, and one of our cases, in spite of an undoubted history of measles plus a dose of convalescent serum, developed a mild measles fourteen days after exposure.

Gunn, working at a fever hospital, particularly with cross-infections, had ample opportunities for controls. His series included wards which were uninoculated, wards inoculated with various animal serums, and wards protected with convalescent serum. His 95.7 per cent. protection, together with our final figures of 98.3 per cent., afford very striking and sufficient proof that until an efficient animal serum is prepared convalescent measles serum is the only weapon we have for preventing measles, and it should be more widely used than it is at present.

MEASLES IN A PUBLIC SCHOOL

BY

L. R. LEMPRIERE, M.B., CH.B.

MEDICAL OFFICER, HAILEYBURY COLLEGE

Epidemics of measles and reports concerning them are not, as a rule, of interest, except to those immediately concerned, but the small epidemic recorded here presents some unusual features. The following is the case incidence:

Case	House	Form	First Symptom	Admitted	Incubation (days)	Source of Infection
Ya.	M.	Vb	May 3	May 3	?	?
Fl.	M	LVl	,, 18	,, 18	15	Ya.
Th.	M.	LMla	,, 18	,, 20	15	Ya.
Me.	B.	LMla	June 3	June 3	13	Th.
Fi.	T.	MVa	,, 6	,, 9	18	Th.
Wi.	B.	LMla	,, 7	,, 9	19	Th.
Ca.	L.	LMlb	,, 7	,, 8	19	Th.
T-D.	B.	LMla	,, 8	,, 9	20	Th.
De-R.	Bat.	UMb	,, 8	,, 10	20	Th.
We.	Tr.	LMla	,, 16	,, 16	10	Ca.
Po.	Law.	UMb	,, 20	,, 20	10	De-R.
Cn.	Bat.	LMlb	,, 23	,, 25	13	De-R.
Met.	Ed.	UIV	,, 27	,, 27	17	De-R.
Da.	B.	UMb	,, 26	,, 28	3 or 17 or 18	Po or De-R or Wi.

The points of interest are the smallness of the epidemic, and the very long incubation period.

In a school of 530 pupils 115 were not protected by a previous attack; normally between 90 and 100 might have been expected to develop the disease, compared with 14 who actually did.

The long incubation period is unique in my experience. The average period of incubation, leaving out that of the first case, which is unknown, and that of the last, which is doubtful, was very nearly sixteen days; in six cases the period was between seventeen and twenty days.

Clinical Symptoms

The cases were definite measles of a mild character, not rubella. Prodromal symptoms appeared in four cases in less than twenty-four hours, in three one day, in six in two days, and in one in three days. Fever lasted for two days in six cases, for three days in five, for four days in one, and for six days in two, the maximum recorded being 104° and the minimum 101°. Conjunctivitis was marked in all cases. Catarrh was present in five cases, absent in nine. Complications included two cases of vomiting, one of epistaxis, and one of adenitis. Rash was very well marked in all cases, but in my opinion no stress can be laid on this, as the rashes of measles and rubella can be, and often are, exactly alike. Koplik's spots were present in all cases, profuse in four, well marked in five, and slight but definite in five. The prodromal symptoms were so slight that all patients, except Fl., when first seen, had a commencing rash and definite Koplik's spots.

Infection Described

The first patient (Ya.) was admitted early on the morning of May 3rd, 1930, the pupils having returned the night before. This boy had been seen by me the previous evening, on account of tinea cruris, and appeared to be perfectly well. Twelve hours later he returned with a well-marked rash and profuse Koplik's spots and fever.

As there seemed to be an unusually favourable chance of preventing the spread of measles, I sent away all the boys with whom Ya. had been in contact and who had not had measles previously, for ten days, from the sixth to the sixteenth day after exposure, and took the temperature of all the boys in his house who had not had measles. As far as he knew, he had not seen them during the twelve hours, between 8 p.m. and 8 a.m., but on the evening of the sixteenth day, both Fl. and Th. felt unwell. Fl. did no damage, but Th., who stayed in school for another thirty-six hours, infected others, as indicated in the table.

I did not regret that my efforts to prevent the spread had failed, because I consider from a strictly medical point of view that measles in the summer term is to be welcomed. The general mildness of the cases is attributable to the character of the disease, the excellent weather, and the small amount of infection, which enabled each patient to be nursed in a large separate room.

Five weeks later, on the last day of the term, a boy developed measles on arriving home, though he had been inspected by me that morning for mumps, which was epidemic at the end of the term. Through him, thirty-two other cases were recorded during the holidays, but it is impossible to relate this outbreak with its predecessor.

Observation

The only observation I have to make is that either Koplik's spots are *not* the absolute diagnostic sign of measles, as is generally held, or that under certain conditions the incubation period of measles may exceed a maximum of sixteen days.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

DERMATITIS CONSEQUENT ON THE APPLICATION OF IODINE

The case of fatal dermatitis following the use of iodine spirit solution, reported by Mr. R. Charles Alexander in the *Journal* of July 19th, 1930 (p. 100), prompts me to relate a somewhat similar case which came under my care.

A fruit merchant, aged 60, had occasion to empty and clean a blocked drain, which took him several hours to accomplish. Both his arms were immersed in the contents of the drain pipe, with the result that they were swollen, the skin having become sodden with the prolonged immersion. He took care to wash his arms thoroughly and often with plenty of warm water and soap, which gave him a sensation similar to that of a shampoo, a very cooling and pleasant effect. Later he thought it would be an excellent thing to paint his arms with iodine tincture; the effect of this a few hours later was of a warm tingling nature. The following night he suffered from intense itching, and came to see me next morning.

Both his arms were acutely inflamed and swollen; they were covered with vesicles turning into pustules, and were extremely painful. His temperature was 103° F., and owing to the swollen condition of his wrists I counted his pulse from the facial artery. He appeared ill, restless, very weak, and toxic. I applied starch poultices to both arms, and ordered a stimulating diet. Four hours later, as he was still in great pain, I removed the poultices, and washed the starch off with a solution of sodium bicarbonate, which gave him much relief, to the extent that he implored me to continue the treatment; later on linimentum calcis with calamine was applied on lint, and this was repeated every four hours, alternating with the bicarbonate washing. His general condition was by next day much improved, the temperature having fallen to normal, and the swelling in the arms having diminished, but the area of pyoderma was still very marked; the bullae were cut away as

they appeared, and the application of the liniment and the soda washing were continued until the whole skin cleared. The condition of the skin later became pigmented and somewhat shiny, with no uncomfortable sequels.

I believe in this case that the acute infection arose, not from what he might have contracted from the contents of the drain, but possibly from the bacteria in the skin becoming pathogenic when the soil was rendered favourable. The skin was soaked in water for hours, and later was washed excessively with hot water and soap, no doubt removing gross dirt and superficial layers of the skin, hence the feeling of shampoo effect. Had it been left at that all would have been well, but the application of tincture of iodine to this tender surface caused an acute irritation, calling the cutaneous staphylococci and streptococci from their dormant state into pathological activity.

I was given to understand years ago that iodine solution applied to washed surfaces was futile, and that its virtue depended on its being applied to unwashed skin lesions. In this case the effect of the starch poultice was to remove or absorb the iodine from the skin, judging by the starch turning purple; this probably arrested its pungent effect. I did not inflict vaccine therapy on the patient, and fortunately the condition improved before an autogenous vaccine could have been prepared, otherwise the credit would have gone to this doubtful remedy. It should be remembered that alcoholic iodine solutions are in their nature irritants; their application to areas already denuded of surface protection, by cleansing the skin, as a preliminary, for example, to surgical incisions, and especially in very tender skins, is open to a risk which is real though remote.

O. THOMAS JONES, L.R.C.P., L.R.C.S.Ed.,
Colwyn Bay. L.R.F.P.S.Glas.

HYDATID CYST OF LIVER SIMULATING SUBPHRENIC ABSCESS

The following case seems worthy of record, as the *x*-ray findings were most misleading, and a diagnosis could not be made until after the second operation.

A woman, aged 30, came to the hospital with one and a half years' history of a swelling in the epigastrium. During the last two months pain had been very severe, and accompanied by high fever and rigors. The patient was obviously very ill; her temperature was 39° C., and her pulse rate 104, and she had much dyspnoea and a tendency to faint. The whole of the upper abdomen was tender on palpation, and a swelling could be seen in the right upper quadrant, with rigidity extending to just below the umbilicus. A tentative diagnosis was made of acute suppurative cholecystitis. On screening the patient in the upright position I was surprised to find a large air bubble, apparently between the upper surface of the right lobe of the liver and the diaphragm. The liver itself appeared to be obscured by a layer of fluid. It was natural, I think, in the circumstances, to make a confident diagnosis of subphrenic abscess due to a long-standing leaking gastric ulcer.

First Operation.—Under novocain infiltration an incision was made just below and parallel with the right costal margin. On opening the peritoneum I was amazed to find that the upper surface of the right lobe of the liver was in contact with the diaphragm, and entirely free of adhesions; the hand could be passed freely between the liver and the diaphragm, and the liver, though somewhat soft and boggy, did not appear particularly abnormal. Accordingly there was nothing to be done but to pack iodoform gauze firmly on to the liver surface, and review the situation.

Second Operation.—Two days later, without anaesthesia, the packing was removed and a large-bore needle was cautiously introduced into the liver substance. There was an immediate escape of foul-smelling gas under high tension. The needle track was enlarged with a scalpel, and a drainage tube inserted into a large and apparently empty cavity. This was followed by the escape of a small quantity of glairy pus.

During the next fortnight an enormous quantity of small hydatid cysts and pus was evacuated. After a few days the pus became deeply bile-stained, and the patient's temperature rose to 40° C., with a pulse rate of 120 and a respiration rate of 28. By the seventh day the patient was convalescent, and she left the hospital at the end of a fortnight. The subsequent course of recovery was uneventful.

It is, I think, remarkable that although the abscess was separated from the general peritoneal cavity by less than 1/2 cm. of liver tissue, no adhesions or visible inflammatory reaction had been formed.

E. H. R. ALTOUNYAN, *M.C.*, M.D.Cantab.
Aleppo, Syria.

Reports of Societies

RADIOLOGICAL PROBLEMS IN VETERINARY MEDICINE

The Sections of Electro-Therapeutics and of Comparative Medicine of the Royal Society of Medicine combined for a discussion, on December 19th, 1930, on radiological problems in men and animals. Professor J. WOODBURN MORISON, president of the Section of Electro-Therapeutics, was in the chair.

Major A. A. PRYER opened by giving some account of the radiology of the horse; he had examined seventy living horses and many cadavers. The difficulties were the bulk and indisposability of the equine patient, the thickness and irregularity of outline of most parts of the horse's skeleton, and the design of suitable apparatus. In some cases he had administered a narcotic—chloral hydrate—before taking the radiographs, and a useful precaution was to plug the ears of the animal with cotton-wool so that it was not startled by the noise of the tube. The shoes must be removed when radiographing the hoof. Almost every part of the horse's body was closed to the radiologist except the limbs, but radiographs of these were very useful. No method had been devised for satisfactorily viewing the pelvis, shoulder, or hip.

Dr. R. W. A. SALMOND mentioned that he once had occasion to examine radiographically the hind limb of a pygmy elephant, and had been impressed by the great density of the hide and soft parts as compared with the human. Smaller animals presented few or no technical difficulties, but the larger ones, such as the racehorse, required special apparatus. Whatever apparatus was used, it should be powerful enough to permit of an exposure in a fraction of a second or less, should be as noiseless as possible, and should not have to be brought nearer than 12 inches on account of the electrification of the hairs of the animal. The most common conditions for which *x*-ray pictures were required were fractures and dislocations, and foreign bodies swallowed or embedded in soft parts. Since greyhound racing had become popular, much work had been done in diagnosing fractured toes and dislocated joints in these animals. It was interesting that the chemical composition of stone in dogs was very similar to that in the human being. In radiotherapy much work had been undertaken experimentally on rats and mice, and the treatment of carcinoma and sarcoma in dogs and cats might be carried out radiologically. The domestic animals were susceptible to practically every variety of malignant neoplasm known to pathology. Radiological sterilization of bitches and female cats by *x* rays might by some people be considered a preferable alternative to spaying.

Lieut.-Colonel MIDDLETON PERRY gave some account of the daily work of the veterinary surgeon in which *x* rays were used. The scope of radiology in veterinary science was small and necessarily superficial. The administration

of a bismuth meal, for example, was a difficult problem. For the present, the use of the rays must be considered as confined to the more obscure fractures, callosities, and foreign bodies. He had always found it useful to have a set of normal negatives for comparison. Ultra-violet radiation and radiant heat treatment were well borne by animal patients, and gave good results. He had not found it necessary to remove the hair in order to get effective ultra-violet application.

Dr. J. B. KING described some research work done in recent years on ovarian function, especially on mice. Various people had tried to influence the oestrous cycle in mice by injections of pituitary extract, and the conclusion had been reached that this gland was the source of the internal secretion which, by influencing the ovary, produced the oestrous cycle in animals. The whole subject was of more than theoretical interest, because there were commercial preparations of ovarian hormones, at the moment not very potent, but likely to be of increased potency in the future, and in both medical and veterinary practice they would have an enormous sphere of utility. This work had been made possible by experiment on a large number of mice sterilized by x rays. The work in this sphere was most likely to be advanced by some means of irradiating the pituitary, preferably in mice; he thought it might be done by a small parallel beam of gamma rays of radium.

Professor J. MCCUNN said that x rays had been used successfully in the localization of odontomas in horses. The sinuses in the horse's head could very well be seen, and it was possible to tell whether the teeth were normal or not. As for methods of sterilization by x rays, on the contrary, some attempts had been made to make sterile animals fertile by this means, and one worker had succeeded beyond doubt in this respect by applying ultra-violet rays. Dr. A. E. BARCLAY showed some radiographs illustrating an observation on the mechanism of swallowing in fowls. The act of swallowing took place, not by propulsion as stated in the textbooks, but by suction. He added that just as radiology had completely changed the face of clinical medicine, so it would change the face of zoology, comparative medicine, and physiology. Dr. J. F. BRAILSFORD showed x-ray slides illustrating the type of cases which were dealt with in conjunction with a veterinary surgeon, and included various conditions found in animals in the Birmingham abattoirs while he was doing research there under Sir John Robertson. Dr. A. EIDINOW spoke on the lethal action of rays. In the laboratory it was definitely possible to kill small animals by visible light alone, also to kill shaved animals by intensive doses of ultra-violet radiation. Research had shown that ultra-violet rays could act only on the surface layers of living tissue, and if there was a mass of hair he could not conceive the rays acting. Any beneficial results obtained by a lamp were not really due to the ultra-violet, but to the light and heat, rays. It was also possible to kill animals with intensive doses of x rays and radium.

Professor G. H. WOOLDRIDGE agreed that x rays should not take the place of manipulation or clinical examination, but should be regarded merely as an auxiliary. In many instances he had been unable to get assistance from, or had even been misled by, the consideration of a well-taken radiogram. The extreme ease with which sterilization could be carried out in animals by ordinary methods made x rays in most cases out of the question. In the field of experiment he was glad that they were likely to reduce or perhaps entirely replace vivisection. Dr. CHALMERS WATSON raised the question of radiation in relation to nutrition in animal life, and urged that the two Sections, together with the Section concerned with public health, should co-operate in the study of this problem.

OBSTRUCTIVE INFLAMMATORY LESIONS OF THE UTERUS

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Sheffield on November 28th, 1930, with the president, Dr. J. W. BURNS, in the chair, Professor D. DOUGAL (Manchester) read a paper on obstructive inflammatory lesions of the uterus.

Professor Dougal opened with a brief historical review to indicate the paucity of the literature dealing with this subject. His subsequent remarks were based on a study of ten cases. He considered that two factors were always present: (1) an infection of the uterus and appendages, and (2) atresia of some part of the genital canal. Since the menses never made their appearance one or both factors must have been present at puberty, and the presumption was that both were acquired during childhood, or that one, the atresia, was congenital, and the other, the inflammatory lesion, acquired at a later date. He defined three classes of his cases: (1) three cases in which the uterine cavity was obliterated; (2) two in which the uterine cavity contained mucus or caseous material—hydrometra or pyometra; and (3) five cases in which the uterine cavity contained menstrual blood—haematometra. An analytical review of the cases described led him to conclude that tuberculosis or some other acute infection of childhood might produce atresia of some part of the genital canal, the result as regards disturbance of function depending upon the situation of the obstruction. In tuberculosis the tubes and uterine cornua were the commonest parts affected, and their canals either became completely obliterated or were distended with pus or blood. If the cavity of the uterus was obliterated, retained secretions or blood might be found in the tubes or cornua; but if the atresia was at the level of the internal os there would usually be haematometra or pyometra. When the obstruction was below the level of the cervix hydrometra was an additional possibility. Professor Dougal remarked that it would be of interest to know something about the frequency of vaginal discharge in these diseases and, more important still, to see the patients about the age of puberty, when it might be possible to find out the extent of the damage to the uterus and appendages. A working arrangement was needed between the hospitals for children's and infectious diseases and the gynaecological hospitals, to ensure that these cases were kept under observation until the effects, if any, on reproductive life had been determined. It would then be possible to trace the origin, not only of the serious lesions which he had described, but also of those less severe cases in which the tubes were sealed up or the ovaries were adherent.

The PRESIDENT and Dr. A. A. GEMMELL each described a case which, in the light of Professor Dougal's remarks, appeared to have been not simple atresia, but the results of chronic inflammatory diseases.

Pathological Exhibits

Professor DOUGAL showed a specimen of chorion epithelioma of the uterus. The history had suggested the presence of retained products of conception, but histological examination revealed the typical features of chorion epithelioma. He considered chorion epithelioma a very rare tumour, worthy of record; he had only come across four cases during the previous twelve years. The specimen was discussed by the PRESIDENT and by Mr. ERIC STACEY (Sheffield), who also showed a specimen of a twin pregnancy, in which a child was born alive, and was followed by the expulsion of a large hydatidiform mole, weighing 10 lb. 4 oz.

A further specimen shown by Professor DOUGAL was a carcinoma in one horn of a bicornuate uterus with a

double cervix. In the right horn there was an advanced growth which had infiltrated the muscle wall and broken through into the lower part of the left horn and both halves of the cervix.

Mr. N. L. EDWARDS (Derby) showed a specimen of an ectopic gestation in a hydrosalpinx. This consisted of the left tube and ovary, with a mole in the isthmic portion of the tube and a small tear in the wall through which intraperitoneal bleeding had occurred. The tube distal to the mole was thickened and in a state of hydrosalpinx. He suggested that the case might be one of direct internal migration of ovum.

Mr. P. MALPAS (Liverpool) showed a large cervical fibroid weighing 10½ lb., with extensive cystic changes, and also a specimen of a cervical fibroid removed subsequent to radium treatment of a coexistent carcinoma cervicis. The sections in this case were of interest in that there was no definite change in the cells of the fibroid.

TREATMENT OF PSYCHONEUROSES

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, held on December 12th, 1930, with Dr. W. G. HARVEY in the chair, Dr. E. ARMSTRONG BENNET read a paper on treatment of the psychoneuroses. Dealing first with the difficulties in recognizing psychoneurotic illness, he said that early diagnosis was important, as instanced by the vast numbers of persons in mental hospitals, many of whom might have been cured if treated at the beginning. Some of the difficulties involved in the acceptance of a psychological causation were considered; the physician untrained in psychopathology was unlikely to diagnose neurotic illness. The inclusion in the medical curriculum of some instruction in the minor mental disorders, in addition to that now given in gross mental disease, was advocated. Some of the problems which arose in dealing with psychoneurotic out-patients were discussed, and the appointment of a psychotherapist to the hospital staff was advocated. Finally, certain therapeutic methods were discussed, including mental analysis, suggestion, and occupational therapy.

Dr. T. G. MOORHEAD felt that the curriculum was already more than full, and suggested that the lectures on mental diseases could include two or three lectures on psychotherapeutics without increasing the actual number of lectures. He was of opinion, however, that facilities should be available for post-graduate study, and pointed out that a diploma in psychological medicine had recently been established in the University of Dublin, and that courses of instruction for the diploma were now provided. Dr. J. O'C. DONELAN said that in most mental cases the removal of physical disorders were followed by mental improvement.

Dr. LAWRENCE KOLB remarked that one of the outstanding practical merits of modern psychotherapy was the emphasis it placed on the subjective or intrinsic factors in human motives and conduct. It had shown that man's adaptive difficulties and maladjustments could not be explained in terms of external causes alone acting upon a passive non-participating organism. The external factors were important, but their effect depended upon our ability to react to them normally, and this in turn depended upon our constitutional heritage or tendencies as they had been modified by various environmental factors. The Freudian school of psychology has focused attention on these subjective factors, and had improved other methods of psychotherapy, such as persuasion, suggestion, simple explanation, etc., by throwing more light on the mode of operation of these forms of treatment. Psycho-analysis at best was applicable only to a selected group of patients. An intelligent subject was essential, and its use in people past middle-age was, as a rule, not advisable. The obsessional neuroses, conversion hysterias, certain sexual abnormalities, and anxiety states, offered the most favourable material, but the magnitude alone of the problem of the neuroses made it imperative that the majority of cases should be treated by the simpler and less time-consuming methods mentioned by Dr. Bennet. Dr. W. M. CROFTON was of opinion that many cases were due to microbic infection, and that immunization by a suitable antigen was often followed by recovery.

Dr. LEONARD ABRAHAMSON said that the confusion in the mind of the general physician in regard to psychotherapy was due to the attitude of the psychotherapeutists, who adopted an obscure terminology, which moreover varied from one exponent to the other. He deplored the lack of unity of approach in regard to the psychoneuroses, and felt that, until this was attained, no widespread use of psychotherapy would be possible. He suggested that in many of the cases labelled psychoneuroses physical causes were present, though these might elude available methods of investigation. It would be useful to have an outline of the treatment adopted in the group of cases in which hypotension was a constant feature and responsible for many of the characteristic symptoms. Professor HAROLD PRINGLE said that he naturally viewed psychoneuroses from a physical standpoint, and felt that recent work on the conditioned reflexes was the clue to the explanation of these affections. He thought that in a psychoneurosis wrong reflex channels had been established, though what exactly caused such establishment he could not say. He felt that the whole aim of treatment should be to reopen the normal channels. If this was done, abnormal reactions and maladjustment would disappear and the patient would be well. Dr. R. R. LEEPER said that the value of the work of the late Sir Frederick Mott could not be exaggerated. Referring to the large number of insane people in Ireland, he said that this was due to the persistent neglect in Ireland of feeble-minded children. Several attempts had been made to get the Mental Deficiency Act extended to Ireland, but they had all failed. Dr. H. T. BEWLEY thought that psychotherapeutists were still groping in the dark because they did not know the changes which occurred in the cells when will and other functions of the mind were exercised. He referred to the folly of telling a nervous patient to "pull himself together"; a depressed, nervous patient was quite unable to do this, and injurious consequences often followed the giving of such advice. Dr. F. C. PURSER said that what impressed him about psychotherapeutic methods was that Freud, Adler, and Jung all had different theories concerning the etiology of the psychoneuroses. They all worked on different principles, and yet they all got much the same results. He recognized that these results were good, but until more uniformity in theory and in practice had been obtained he could not feel that one was standing on firm ground. At present he felt that treatment was quite empirical.

Dr. BENNET, in reply, said that many psychoneurotic conditions tended to become psychotic. At the Tavistock Square Clinic the majority of patients were men, and three out of four patients that he saw in his private practice were men. The Freudian system was at present undergoing considerable changes. There was no unity of approach, and therefore the whole subject was rather confusing, but it appeared to be a sign of life that psychotherapeutists were still searching for a cure. He thought that Sir Frederick Mott had explained the pathological basis of dementia praecox, but he had not given any explanation of the mental state, and had approached the disease from a purely pathological basis.

Reviews

PRINCIPLES OF BIOLOGY

Professor LANCELOT T. HOGBEN's recently published book on the *Principles of Animal Biology* has the merit of living up to its title. It is, in the first place, concerned strictly with the general principles of which the phenomena of living matter are manifestations, presenting no more of the anatomical and physiological facts than are necessary to illustrate these principles; secondly, it deals exclusively with biology—the science of *living* things—and not, as do many works bearing a similar title, with the architecture of corpses. The author has made a complete break with the traditional "type system" which, introduced by Thomas Henry Huxley, still forms the basis of most English textbooks for first-year students. In this way he not only spares the student the irksomeness of meeting again facts with which his laboratory manual has made him sufficiently familiar, but leaves himself free to *develop in a logical manner the principles of scientific* method in general and their application to biological science in particular. Wherever necessary he has adopted an historical approach, "in the belief that the student will not attain to a sense of the challenging quality of scientific thought, unless he realizes the steps by which our present knowledge has been reached." It is this sense of the profound value of precise and disciplined observation and thinking, of the worthlessness of metaphysical speculations not rooted in scientific knowledge, that Professor Hogben succeeds in conveying to the reader throughout this book.

The work falls logically into two parts: the first, in which the elementary facts of comparative anatomy, with strict reference to their physiological significance, are set out in their proper order; the second, in which these facts are used as a basis for the interpretation of the phenomena of living matter. Of special value are the chapters on the machinery of inheritance and on the evolutionary problem, the former presenting a lucid account of the fundamental facts of genetics, the latter a scholarly and philosophical statement of the controversies that have raged about the problem of the origin of species. Professor Hogben, not unmindful of the possibility that "many . . . will shake their heads at the introduction of so much new and controversial material into a book of so elementary a character," is ready with his defence. "I have found in teaching," he says, "that young people are not interested in a dead subject, but are attracted to what is —like themselves—in a stage of rapid growth; and in my experience the surest way in which to make dull facts palatable is to make them topical." To the intelligent student, above all to the student who can take pleasure in science in the making, who would rather have his mind stimulated than crammed with sterile facts, this book may be unreservedly recommended.

SURGICAL DYSPEPSIAS

Mr. A. J. WALTON's well-known monograph on *The Surgical Dyspepsias*[2] now appears in its second edition. There can be no two opinions about whether he has succeeded in his endeavour to give a fair and just account of what is sometimes called "upper abdominal surgery." The book is unique, for it combines a most exhaustive review of the literature of the various lesions with a careful analysis based on the author's great and varied experience. As to that experience, he is now able to refer to his 1,186 cases of gastric and duodenal ulcers, 271 cases of carcinoma of the stomach, and 546 gall-stone patients operated upon. His own careful records and follow-up ensure that his judgements are based on mature consideration, not only of the immediate, but of the late, results.

The labour of producing an intensive study of this magnitude must have been immense. It is true that the reader may still hanker after a shorter and more concise account, possibly limited entirely to what Mr. Walton himself thinks. But it is a fact that great clinical and operative experience do not in themselves qualify an individual for omniscient and dogmatic statement on the whole range of etiology, pathogenesis, and morbid physiology, though it is not everybody who recognizes this. The great number of authorities quoted and the alternatives given have been inserted, we feel sure, for the purpose of the fullest possible discussion, and the reader may judge the issues for himself. The careful reader will find that the author does declare himself for one view when several are possible, but the declaration is very modestly made. Mr. Walton is no believer in the virtues of medical treatment for peptic ulcer, and the surgeon whose morale has been shaken by the recent advocacy of conservatism will find new encouragement in these pages. But he will find it on all the subjects treated of in this masterly volume.

ANGINA PECTORIS

Angina Pectoris,[3] the title of Dr. BROOKS's pleasing little monograph, inevitably recalls to the mind what Professor Ernst Edens, in his book on diseases of the heart and the arteries, wrote on the subject: "The diagnosis of angina pectoris cannot always be as certainly established as the patient and his doctor would like. Huchard says 'there are not several anginas but only one, coronary angina, the others being false. And if one cannot distinguish between them, I wonder what is the use of Medicine.' Osler is less confident, 'A cocksure diagnosis may express the assurance of ignorance.'" Where such men as Huchard and Osler have not seen eye to eye we may be allowed to note with interest the announcement of any new methods of diagnosing and treating this disease, and Dr. Brooks's book is therefore not unwelcome.

The difficulty about angina is that it is entirely subjective, for even the electrocardiogram during an attack is normal. It is a symptom relieved by certain drugs which dilate the coronary arteries and improve the blood supply to the heart; upon this supposed effect of amyl nitrite and its congeners is based the more widely accepted view of the pathology of the condition, that it is caused by disease of the coronary vessels, which are indeed in a large proportion of cases (but not in all) found at necropsy to be abnormal. It is not quite so simple as that, for the condition is rather a symptom-complex, and therein lies the source of the confusion which prevails, as the symptom-complex is in turn ill defined. Yet we condemn some of our cases to inactivity and early extinction, but others we invite to lead lives of normal usefulness and to reach a good old age. Mistakes are made, but diagnostic errors are not unknown in the case of other diseases. In all forms of cardiac disease optimism is desirable and, as we know now, well justified; in angina we are in the happy position of being at times sufficiently uncertain of the diagnosis to be able to give the patient the benefit of our doubt. In the prognosis of cases diagnosed with certainty we may base our estimate on the response to effort, and we shall fall short of accuracy less often than those who utilize other criteria.

[1] *Principles of Animal Biology*. By Lancelot T. Hogben, D.Sc.Lond. London: Christophers. 1930. (Pp. xxiv + 332; 125 figures. 8s. 6d. net.)

[2] *A Text-Book of the Surgical Dyspepsias*. By A. J. Walton, M.S., M.B., B.Sc., F.R.C.S. Second edition. London: E. Arnold and Co. 1930. (Pp. viii + 726; 286 figures. 42s. net.)

[3] *Angina Pectoris*. By Harlow Brooks, M.D. Medical Monographs. London: A. and C. Black, Ltd. 1930. (Pp. viii + 164. 6s. net.)

Dr. Brooks sets out in a very readable form what is generally accepted about this disease, and is very optimistic in tone. It is difficult to find any strikingly new observation or original method of treatment in his book. The chapter on surgical treatment is a very good summary of a complicated subject, and the author wisely refrains from expressing an opinion on the results, few of which have fallen under his notice.

LAST LECTURES BY RUDOLF MAGNUS

The late Professor Rudolf Magnus was invited in 1927 to give the Lane Medical Lectures in Stanford University School of Medicine. Their delivery was prevented by his tragically sudden death in that year, but he had already prepared the lectures, and these have now been published.[1] Dr. H. H. Dale has written an introductory note recounting Magnus's great services to pharmacology and experimental medicine, and a list of his published works is appended. Two lectures deal respectively with the experimental pathology of the lungs, and the action of choline as an intestinal hormone, while the third and last lecture is entitled "The physiological *a priori*." The second lecture is of particular interest because all the fundamental work on the action of choline upon the intestine was done in Magnus's laboratory. Weiland and Le Heux showed that the choline diffused out from the isolated gut into surrounding fluid, and that the gut only functioned in a normal manner in the presence of choline. Further investigation showed that intravenous injections of choline produced powerful stimulation of the intestinal movements in the intact animal, and that they could overcome gastro-intestinal paralysis produced by a variety of causes, such as laparotomy and peritonitis. These results were applied clinically in Germany for the relief of post-operative gastro-intestinal paralysis. Magnus summed up this interesting series of researches as follows:

"This development of the incidental observation of Weiland has led us into very different fields of medicine. It has brought us into contact with physiology, pharmacology, experimental pathology, internal medicine, and surgery, and has unveiled a number of interesting facts of theoretical and practical significance. This is a characteristic feature of pharmacological work. Pharmacology is connected with almost every part of medical art and science, and by the elaboration of her problems the pharmacologist has the pleasure of close and fruitful contact with his colleagues in many different branches of our noble profession."

RADIOLOGY IN NEUROLOGY

A new book on the use of electricity and radiation in the diagnosis and treatment of nervous diseases[2] has been prepared by two Paris physicians, Drs. ZIMMERN and CHAVANY. It is comprehensive, and covers the whole subject as far as is possible in a moderate-sized volume. There are 654 pages and 254 figures. The work is divided into four parts, dealing respectively with electro-diagnosis, radio-diagnosis, methods of treatment, and affections of the nervous system. Each part is very thoroughly treated; the material is concisely put together, and is clearly expressed. The authors are to be congratulated on the way in which they have handled the subject.

Part I opens with the electrical reactions of the motor nerves and muscles in normal and pathological conditions, and a description is given of the methods adopted and the results obtained; it is well illustrated with diagrams of the apparatus employed. A list of lesions is given in which reaction of degeneration occurs in different parts of the body, and the significance of these reactions is discussed. Space is also devoted to electricity in the diagnosis of sensory nerve lesions. A chapter is included on electromyographic methods, and Siemen's electrocardiograph is described. Part II deals with the radiological examination of the nervous system, with a detailed description of methods for examining the skull and spine by ventriculography and encephalography. This part of the book is very well illustrated with diagrams of the distribution of air in the skull and ventricles of the brain. Examination of the central nervous system by means of lipiodol is given at length. Part III records methods of treatment. Faradization, galvanization, ionization, and diathermy are described, and a short chapter is devoted to the radiosensitivity of nerve tissues and the biological effects of radiation. Another chapter deals with actinotherapeutics, and with infra-red and ultra-violet rays.

The concluding part, on affections of the nervous system, deals systematically with these affections in different parts of the body. The chapter on cerebral tumours is exceedingly well written. Radio-diagnostic methods and craniography are described, and are illustrated with various skiagraphic representations of cerebral tumours. Part of this chapter is also devoted to hypophyseal lesions, hemiphlegia, epidemic encephalitis, and myasthenia. Affections of the spinal cord with their diagnosis and treatment are next dealt with. An important chapter is that which deals with compression and tumours of the spinal cord. Traumatic affections of the nerves—facial, brachial, sciatic, and of the lower limbs generally—are treated on similar lines. There are chapters also on muscular affections, myopathies, and congenital muscular atrophy. Under the general heading "Para-neurological syndromes," chapters are devoted to the following affections: exophthalmic goitre, tetany, hysteria, occupational nerve affections, and neurasthenia.

This book is a valuable addition to literature on nerve affections, and should find a place in every medical library. It is particularly helpful to the electrotherapeutist and the radiologist.

MRS. DOSE THE DOCTOR'S WIFE

Dr. Dose and his happy family must be familiar to most medical men with happy families of their own, and in *Mrs. Dose the Doctor's Wife*[3] Miss JOYCE DENNYS with pen and pencil discloses some of the secrets of this lady's family life. We seem to remember a feeling of doubt raised by the distinctly unflattering portraits of Dr. and Mrs. Dose as to the possible loss thereby of parental dignity in the eyes of the young, a doubt which appears to have been only too well founded in the case of Miss Dennys. The six sketches of Mrs. Dose are introduced with the explanation that all doctors' wives wear false noses to conceal their little insincerities from the public gaze, and they are illustrated in the happy and amusing style with which we are so familiar. One need say no more than that the text is thoroughly in keeping with the illustrations. Should Mrs. Dose be tempted to feel a little hurt at the somewhat ruthless exposure of her disguise we would bid her remember that there are very few individuals in this world who can afford to face the public eye without a false nose, and that most people require more than one.

An amusing trifle for all doctors and their wives who can enjoy a good laugh against themselves, even if the mirror in which they are reflected produces an unflattering distortion.

NOTES ON BOOKS

Within two years of the publication of a second edition of ROMANIS AND MITCHINER'S *Science and Practice of Surgery*,[7] a third edition has been called for, which proves beyond all doubt that the book fulfils the object for which it was written. There is no need to enter into a detailed review of a work which has so evidently come to stay. For the purpose of the latest edition a general revision of the text has been carried out, while the section on whitlows has been rewritten and enlarged, and that on varicose veins revised and amplified with regard to the details of treatment by injection. Certain portions of the chapters dealing with cranial lesions and fractures have been largely rewritten, and much new material has been added to the treatment of burns and empyema, and to radium therapy and anaesthesia. Some new and additional illustrations and plates appear. This third edition should prove as acceptable to students and practitioners as the preceding editions have been.

Fortunately for the reader of *The Formenkreis Theory and the Progress of the Organic World*[8] the author reproduces his central idea in the form of a diagram towards the end of the book. The diagram has in its centre a sun—the sun of life—from which emerge rays, each ray representing a particular form of life. Thus the human and anthropoid rays are distinct from their point of emergence from the central disc. "Formenkreis" is another name for a "real" species, which the author alleges was first defined by Immanuel Kant in 1775. The author is evidently a student of birds, and many of his illustrations are drawn from the bird world. The problem of man's origin is discussed, but no fresh light is thrown upon it.

How, unless he is a child himself, is the reviewer of children's books to know if the books that give him pleasure are likely to give pleasure to children also? Mr. AUSTIN PRIESTMAN'S "*Gabriel*,"[9] for example, cannot fail to delight the adult reader. The author has a delicate perception of the mind of the child; he can suggest unobtrusively the animism of the child's world, and the continuity of reality and fantasy in the child's life; he writes as an accomplished literary craftsman; above all, he can tell a story. But all these, except the last, are an adult's criteria of excellence, though it is probable that a work that fulfils them is more likely to give pleasure to children than one that does not. The chance is worth taking; Gabriel, if he is the child we take him for, would be glad to see his nursery bookshelf enriched by this beautiful book.

The character and scope of the gigantic treatise on Chemistry[10] now being prepared by MELLOR has already been described in these columns in individual references to the nine volumes already through the press. Volume x, which is now ready, comprises the chemistry of sulphur and selenium, and so exhaustive is the treatment of the subject that there is room in it for no more than the chemistry of these elements. The question, "Where can I find out?" becomes ever more frequent in modern chemistry. The answer is now growing to be a commonplace. "If it is anywhere, you will find it in Mellor." The finished series is to consist of thirteen volumes, and will be without question the most comprehensive work of its kind that has yet been produced.

[7] *The Science and Practice of Surgery*. By W. H. C. Romanis, M.B., F.R.C.S.Eng., and Philip H. Mitchiner, M.D., F.R.C.S.Eng. Vols. i and ii. Third edition. London: J. and A. Churchill. 1930. (Vol. i, pp. x + 772 + 73; 351 figures, 11 plates; vol. ii, pp. ix + 950 + 73; 316 figures, 3 plates. 14s. each volume.)

[8] *The Formenkreis Theory and the Progress of the Organic World*. By Dr. Otto Kleinschmidt. Translated by the Rev. F. C. R. Jourdain. London: H. F. and G. Witherby. 1930. (Pp. 192; 16 plates, 53 figures. 16s. 6d. net.)

[9] "*Gabriel*." By Austin Priestman. London: Alston Rivers, Ltd. 1930. (Pp. 80; illustrated. 3s. 6d. net.)

[10] *A Comprehensive Treatise on Inorganic and Theoretical Chemistry*. By J. W. Mellor, D.Sc., F.R.S. Vol. x. London and New York: Longmans, Green and Co. 1930. (Pp. viii + 958; 66 figures. 63s. net.)

The third edition of PINEY'S *Recent Advances in Haematology*[11] maintains the standard of the previous editions. In the new chapter on "Anaemias with low colour index" there is no mention of the volume of the blood, or reference to the important work of Rowntree and Brown on the application of blood volume estimation as a routine clinical procedure. There is also a new chapter on "Sickle cell anaemia." It seems a pity that Dr. Piney is so limited in the scope of his subject by the boundaries of other books of this excellent series.

The Technique of Medical Treatment,[12] by Dr. G. MILIAN of Paris, is something rather different from what one would expect from its title. It is a compact and attractive volume containing clear and sound instructions for the performance of the minor diagnostic and therapeutic measures on the borderlines of medicine and surgery. Accordingly, there are full and clear accounts of the technique of lumbar puncture, blood transfusion, local anaesthesia, and the uses of trocar and cannula in the various serous cavities, and so forth. Similarly, there are useful chapters on topics such as the common and less serious maladies of the urinary tracts, artificial respiration, and the mechanics of the digestive tract. The authors hope that the volume will be consulted by practical physicians, and we think that the book will be very useful as a handy work of reference for anyone, senior or junior, who wants to be sure of "exactly how to do it." In addition to technical instructions there are very valuable discussions of the various methods and their utilities along orthodox lines.

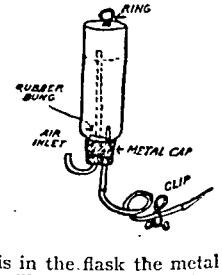
PREPARATIONS AND APPLIANCES

A SIMPLE THERMO-SALINE APPARATUS

Dr. E. M. R. FRAZER (Newhall) writes: Practitioners who are called upon occasion to perform saline infusion into the breast or rectum will at once appreciate the difficulty of keeping the saline solution at the correct temperature; the infusing into the tissues takes some time, and the temperature rapidly falls. This difficulty may be easily circumvented as follows. A cheap vacuum flask of a quart capacity is fitted with a rubber bung. Two pieces of plated tubing, similar in bore to stethoscope headpiece tubing, are obtained, one being about 14 inches long and the other about 6 inches long. These are pushed through the rubber bung fairly close to its centre, the shorter piece just piercing the bung; the other piece is bent through 180 degrees about five inches from the bung. A hole 1 inch in diameter is cut in the metal cap of the flask, and the tubes are passed through this. When the rubber bung is in the flask the metal cap may be screwed on as usual, and will prevent the rubber bung from coming out of the neck. The rubber tubing with the spring clip tap may be connected to the short tube; the long curved tube allows air to enter the flask. A ring for hanging the flask may be fixed to the bottom of the case. The whole apparatus takes up little room, and is easily sterilized. The illustration should make the idea clear.



ABRODIL FOR INTRAVENOUS PYELOGRAPHY

Abrodil (Messrs. Bayer Products Ltd.) is a complex organic iodine compound evolved for the purpose of pyelography after its intravenous administration. It has the chemical formula of mono-iodo-methane sulphonic acid. The iodine content is 52 per cent. It is freely soluble and heat-stable, and solutions can be sterilized by boiling. The dosage recommended is 20 grams dissolved in 100 c.cm. of distilled water. The optimum time for pyelography is fifteen to twenty minutes after the injection. The makers claim that the compound is tolerated almost as well as sodium chloride, and that it is rapidly and completely excreted in the urine without undergoing any decomposition in the body.

British Medical Journal

SATURDAY, JANUARY 3rd, 1931

CANCER OF THE LUNG

In his preface to Dr. Maurice Davidson's book on *Cancer of the Lung*,[1] Professor Arthur Hall lays stress on the importance of knowing the varied and insidious disguises which early pulmonary cancer may assume, so that, acting upon such knowledge, the practitioner may help more than anyone else in forwarding advance in the treatment of this grave disorder. Dr. Davidson, like many other observers, has been impressed by the alleged increase in the incidence of primary cancer of the lung. Walshe in 1878 remarked that cancer of the lung, though very much less rare than had been until recently supposed, was, absolutely speaking, an uncommon affection. Davidson, in his survey of the statistical aspects of the disease, quotes many authorities who refer to the post-war increase in the occurrence of cancer of the lung, one of the most impressive being Hoffmann, who shows that in the United States deaths from cancer of the lung occurred at the rate of 0.6 per 100,000 of the population in 1914, and that in 1929 the rate had risen to 1.9 per 100,000. In the Paris mortuary registers, quoted by Wilson Fox in 1891, cancer of the lung accounted for only 0.09 per cent. of all cases of malignant disease; Lubarsch, analysing cases from all over Germany in 1920–21, found that carcinoma of the lung composed 5.4 per cent. of all carcinomata. All the most reliable figures are based on post-mortem evidence, and they point to a post-war increase so remarkable that it can hardly be explained as being due to improvement in diagnosis or to selection of cases for admission or for necropsy such as might occur in teaching hospitals. Maxwell and Nicholson[2] agree with these conclusions, and add the astonishing statement that in the last five-year period no less than one-seventh of the malignant tumours in the post-mortem room at St. Bartholomew's Hospital took their origin within the thoracic cavity; so that Walshe's remark that cancer of the lung is, absolutely speaking, an uncommon affection, would appear to be no longer valid.

Primary cancer of the lung originates, in the majority of instances, as bronchial carcinoma, although in rare cases it may arise from the alveolar epithelium. In discussing the suggested explanations of the increased incidence of cancer of the lung, Davidson remarks that the intrinsic difficulty is our ignorance of the etiology of cancer generally. The facts as to sex and age incidence are not in dispute; lung cancer affects men more than women, and the average age incidence is round about 50, but Davidson believes that it affects a larger proportion of comparatively young people than formerly. Maxwell and Nicholson show that the increase affects both sexes equally, quoting West, who in 1897 found a sex ratio of three males to one female, and giving their own series as eighty-three males to seventeen females, a ratio of nearly 5 to 1, while Davidson gives almost identical figures from the series at Brompton—eighty-nine males to eighteen females. There is something in occupational environment, as shown by the frequency with which it occurs among workers whose occupation exposes them to constant pulmonary irritation. But the chief evidence of an occupational factor is drawn from the high incidence of cancer of the lung among the miners of the Schneeberg district in Saxony. Davidson, as well as Maxwell and Nicholson, refers to the possibility that petrol fumes, dust, and tar from the roads, furnish etiological factors from which few can escape, but he does not consider that definite conclusions on this point are justified.

The clinical recognition of cancer of the lung is beset with the same difficulties as that of cancer elsewhere. The onset of symptoms is so insidious that the condition is usually far advanced before the patient has need of medical advice. Davidson, however, points out that in a fair number of cases there is a sudden development of some serious manifestation, which may bring the patient to the doctor, and he describes how the cases fall into certain broad groups, as follows: (1) cases with haemoptysis; (2) pleurisy with or without effusion; (3) cases whose history and physical examination suggest some localized infection within the chest; (4) cases with respiratory symptoms other than the foregoing, especially chronic bronchitis, whose condition and physical signs do not suggest any serious organic chest lesion; (5) cases in which the diagnosis is fairly obvious, owing to pressure signs and symptoms. These hints as to the class of case in which cancer of the lung or some other intrathoracic tumour is to be suspected are of more practical value than a detailed analysis of signs and symptoms. The clinical picture presents a good deal of variation; pathological examinations of the sputum, of the blood, and of pleural exudates may only too often yield little or no information, and even the most expert radiological assistance may not give conclusive evidence.

Davidson's detailed case reports serve to illustrate the inherent difficulties of diagnosis, even with every known adjunct to physical examination. Radiological examination, while not infallible, offers the greatest help in the discovery of intrathoracic neoplasms, and Davidson's illustrations of *x*-ray appearances, with and without the addition of lipiodol injections, serve to emphasize the importance of this method of investigation. He insists, and rightly, that the clinician and the radiologist must co-operate. He says: "The use of *x* rays in the diagnosis of non-tuberculous diseases of the lungs has not received such general recognition in this country as it has on the Continent, and especially in the United

[1] *Cancer of the Lung, and Other Intrathoracic Tumours.* By Maurice Davidson, M.D., F.R.C.P. With a foreword by Arthur J. Hall, M.D., D.Sc., F.R.C.P. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (17s. 6d. net.)

[2] Maxwell, J., and Nicholson, W. A.: A Clinical Study of Bronchial Carcinoma, *Quart. Journ. of Med.*, October, 1930, xxiii, 29.

States." To those who watched the growth of radiological examinations in connexion with war wounds of the lungs this is a startling indictment. One would have supposed that a lesson the war had taught for good and all was that *x* rays were at least of equal importance with the stethoscope for intrathoracic diagnosis. Davidson would have the clinician spend much of his time and study in the *x*-ray department. He might have gone further, and said that the patient nowadays may justly complain if a physician ventures to pronounce an opinion upon diseases of the chest of almost any sort without *x*-ray examination. Bronchoscopy, too, has come to be regarded as an integral part of the examination of the chest, and Davidson emphasizes its value in cases of intrathoracic new growths, not only because it may reveal the presence of bronchostenosis, but because the actual growth may in some cases be recognized by direct vision and portions removed for microscopical examination. Finally, he advocates surgical exploration of the chest as a proper step in the scheme of examination now that, as he writes, the technique of intrathoracic surgery has reached a stage in which it presents difficulties no greater than those of opening the peritoneal cavity. He advocates surgical operation, not only as a means of diagnosis, but on the grounds, first, that an intrathoracic tumour may prove at operation to be benign and operable; secondly, that even in regard to proven malignant growths of the lung, unless we are prepared to explore these with the object of exploiting to the full every possibility of surgery, either alone or in combination with radium, we cannot hope to make any real advance.

Dr. Davidson's conclusions will command general approval; his book is full of informing facts, his judgement is reasoned, and his illustrations are both ample and artistic. This monograph is a valuable contribution to medical literature.

MEDICAL BENEFIT AMENDMENT REGULATIONS

During the past year three major matters in connexion with Medical Benefit under the National Health Insurance Acts have been the subject of discussion between the Ministry of Health and the Insurance Acts Committee as representing insurance practitioners. They have related to the procedure to be adopted in reference to: (1) questions of slack certification, (2) questions whether a substance or article supplied to an insured person is a drug or appliance forming part of medical benefit, and (3) questions as to the method by which an insured person may change his doctor. The first two of these matters are the subject of amending Regulations recently made by the Minister of Health (Statutory Rules and Orders, 1930, No. 781), and the procedures laid down in the new Regulations are of considerable importance.

Failure to exercise reasonable care in the issue of certificates of incapacity must be distinguished both from false certification and from breaches of the certification rules which are part of an insurance practitioner's terms of service. The putting of his signature to a statement he knows to be untrue is one of the gravest faults with which any medical practitioner can be charged, and may deserve the utmost penalty imposable either under the national health insurance scheme or by the General Medical Council. Breaches of the certification rules may be of very varied degrees of culpability, and by the existing Regulations may be referred by an approved society for investigation by the Medical Service Subcommittee of the area. Repeated breach of these rules may, in itself, constitute laxity of certification; but laxity usually results from a want of proper care in forming an opinion as to incapacity, or from the practitioner directing his mind to questions other than those that arise strictly from the narrowly defined "sickness benefit" for which the patient is insured. There is no reason to suppose that practitioners have suddenly become more lax in this matter than they were during the earlier years of national health insurance; and the Insurance Acts Committee is of opinion, confirmed by independent inquiries by the Ministry of Health, that slackness in certification cannot be one of the main causes of the increased claims for sickness benefit which have been so serious a feature of approved society experience for the past few years, at least up to the end of 1929. Nevertheless, so far as it exists, it is in everybody's interest to check it, and the Insurance Acts Committee itself initiated the proposals now embodied in the amending Regulations. These have been agreed upon between the Minister and the Committee, and maintain the principle for which the Committee has contended, that questions of this kind are mainly, and in the first instance at least, matters of professional opinion or conduct, which should be judged by a purely professional tribunal. The Minister may refer any case in which the question of slackness of certification arises to a Panel Committee or a committee representative of several Panel Committees, and they, after following a prescribed procedure, are to be the judges as to the facts of the case and its gravity, and are to recommend to the Minister the action he should take. There are provisions for appeal from the findings of the Panel Committee to a special tribunal, and also for the setting up of a composite advisory committee whom the Minister will consult before any penalty is actually inflicted on a practitioner. It is much to be regretted that in this matter the Scottish Department of Health has shown itself less far-seeing and broad-minded and reasonable than the Ministry of Health: the result in Scotland is that the proposals have been withdrawn altogether.

The Regulations that prescribe the procedure to determine whether a substance supplied to an insured person is or is not a drug within the scope of medical benefit are not part of the disciplinary machinery. In this case it is clearly proper that the Insurance Committee and the Pharmaceutical Committee of the area should have a more prominent place in the machinery.

The former committee here has the right of referring a case to the Panel Committee, and both these committees have the right of being heard by the Panel Committee. The practitioner who orders the substances has his interests fully safeguarded, but it is clearly important to protect the Drug Fund from being misused for the supply of foods or toilet articles.

New Regulations dealing with the method by which an insured person may change his doctor have not yet been issued. The proposal is that an insured person on a doctor's list, who has not removed out of that doctor's area of practice, shall only be allowed to change his doctor at the end of a quarter, and then after having given a month's notice of his desire to change. In this matter, unlike the other two discussed above, the Insurance Acts Committee is not in agreement with the Ministry, so that here the will of the approved society officials is to be imposed by the Minister on insurance practitioners in spite of their appeal for postponement at least, and of their strong expression of opinion that the alteration would not be for the good of the service or to the advantage of insured persons. Further comment may become necessary if the Minister takes the action indicated, but it may be said at once that this is not the first time that the officials of approved societies (with the exception, perhaps, of some of the older friendly societies) have shown that insurance practitioners know more about insured persons and feel more concern for their interests than do those officials.

QUININE THERAPY IN MALARIA

The cinchona tercentenary celebrations at the Wellcome Historical Medical Museum were continued on December 15th and 17th, 1930, when further addresses by leading authorities in pharmacy and medicine were delivered. Mr. T. E. Wallis spoke on certain aspects of the study of cinchona, describing work as a result of which the pharmacognosist was able to define the bark most suitable to the physician, to control the identity of the whole and the powdered drug, to analyse materials containing the drug, and to suggest new directions in which the bark may possibly be still further utilized. Major-General Sir Charles MacWatt, who was Director-General I.M.S. from 1922 to 1926, gave an account of his experience of epidemics of malaria in British India, mentioning that for twenty-five years in India he had taken a daily ration of quinine as the only means of keeping himself free from recurring attacks of chronic malaria. He also spoke of cinchona cultivation in India. There were Government cinchona plantations in the Nilghiris in South India, in the Darjeeling district in Bengal, and a quinine factory in the Madras and Bengal provinces. A crop of cinchona rendered the soil, at least for some time, incapable of producing a satisfactory second crop; so that an unrestricted area of suitable forest land was required to enable the earth rendered sterile by the first crop to be abandoned and another crop to be planted on virgin soil. In his opinion the time had come for further efforts to increase the production of cinchona and quinine within the British Empire. In India the production of cinchona could be greatly increased by extending the area under cultivation and by more intensive cultivation. The final address was given by Dr. P. Manson-Bahr, on quinine therapy in malaria from the aspect of the practical physician. He said that of the three species of malaria parasites causing three clinically distinct diseases the benign tertian and the subtertian were the most generally distributed, and the quartan the most infrequent. Subtertian fevers were most amenable to quinine therapy, the other two much more refractory. The primary attack was more susceptible to treatment than were relapses. The resistance of the body to infection was often overlooked; in addition to specific therapy, every other aid must be enlisted to augment the *vis medicatrix*. Lowering of body resistance in a debilitating tropical climate was the underlying cause of the apparent failure of quinine therapy. Quinine exerted its maximum effect if given when the acute paroxysm was declining and the patient was beginning to sweat, for at that moment the parasites had sporulated and the merozoites were free in the blood plasma and most susceptible to the action of quinine. A good method for removing the bitter taste was to prescribe it in a mixture with 10 grains of citric acid, to which were added 4 grains of ammonium carbonate, and 20 grains of potassium bicarbonate. Even by continuous quinine therapy the non-occurrence of relapse could not be guaranteed; and in order to avoid relapse the resistance should be built up by good food, fresh air, and moderate exercise. There were grounds for thinking that in the quiescent stage salvarsan had some action on the parasite, or at least exerted a definite tonic action on the body, so that he was in the habit of combining one or more injections of 0.3 grain of neosalvarsan as adjuvant to quinine therapy. He was sure that quinine did not exert its maximum effect unless the intestinal tract was in a receptive state for its absorption; therefore a saline aperient should be given at the commencement of quinine treatment and thereafter once or twice weekly. In subtertian infections such large doses were not needed as in benign tertian. One could commence with 15 grains of the alkaloid in solution, generally given by the mouth (except in the more severe clinical forms, with bilious vomiting, when a smaller amount should be given intramuscularly), and the dose by the mouth could be gradually increased to 30 grains daily. In very severe toxic cases of subtertian infection the pushing of quinine must be avoided on account of the liability to blackwater fever. Finally, Dr. Manson-Bahr mentioned plasmoquine. He believed this compound a useful adjuvant to quinine treatment, and in many circumstances an efficient substitute. It had certainly opened up vistas the exploration of which might yield less toxic and even more specific antimalarial drugs.

A COURSE IN PSYCHOLOGICAL MEDICINE

During the past three months a series of twenty-four post-graduate lectures on psychological medicine has been given by two prominent members of the staff of the Tavistock Square Clinic for Functional Nervous Disorders. Dr. G. Graham Howe dealt with mechanisms of the mind at 3 p.m. on Wednesdays, while at 4.30 p.m., after an interval for tea, Dr. H. Crichton-Miller discussed psychological types. The success of the enterprise can be gauged from the fact that the

clinic held no room large enough to accommodate the class, and the hospitality of Friends House, in Euston Road, had to be enlisted. The lecturers between them provided a bill of fare which was long but not indigestible. Its courses were skilfully blended. Many of the ingredients used would have been little relished unless presented with discretion and garnished with common sense. Only connoisseurs could guess how arduous must have been the service which prepared them. Dr. Howe, in indicating psychological mechanisms so far as they are at present understood, followed no one school of thought, but drew impartially—from Freud, Jung, Adler, and others—contributions which exposed the direction of paths still unexplored. While some of these are likely to remain blind alleys, others may prove to be thoroughfares to a realm of more complete understanding of human minds and motives than any of us can conceive at present. On the whole, Dr. Crichton-Miller had set himself an easier task in outlining "type psychology." The reaction of the individual to influences whose genesis might extend back far beyond his own life was, he said, modified by his type, and examples wittily drawn from clinical practice confirmed the value of this method of approach. The lecturer was careful to point out the rarity of pure, uncompensated types; but the temptation to label the pronounced "feeling" and "thinking" types among their friends and patients was not likely to be resisted by his audience. The tact with which both lecturers handled their subjects would merit praise, were it not impertinent to offer praise on this ground to professional psychologists. They recognized that medical practitioners attending a post-graduate course on any subject are prepared as a rule to listen attentively, but not to work between lectures; for their escape from practice, even for a brief couple of hours, is costly enough. If further effort in the way of home reading is required in order to follow the argument, the attendance at the later part of a series of twelve sessions tends to flag. That no such tapering marred the good relations between these lecturers and their eager class is a tribute to the consistent level of the instruction offered.

READING AND EYE MOVEMENTS

A series of delicate experiments have been carried out at the psychological laboratory in the University of Cambridge on the movements of the eyes in reading. The results appear in one of the monographs published by the Medical Research Council.[1] Most people have some appreciation that the fixation of the eyes is not completely steady, for the after-images of a bright light, looked at for one moment, are several and not one. In this piece of work Miss Vernon has investigated the effects of different factors, such as meaning, interest, and trains of thought, on the effector mechanisms of reading, these effects being judged by observation of the ocular movements and of the rate of reading. The observations were made with the help of a most ingenious apparatus, which recorded the ocular movements by photographing a beam of light reflected from the cornea of the eye upon a continuously moving film. It was found that the eye did not remain steady during voluntary fixation. With a fixation period of twenty seconds, long drifts, shorter waves, and rapid jerks away from the fixation point were shown by most subjects, and similar drifts occurred during the shorter fixation periods. Voluntary movements were performed accurately in only 20 per cent. of cases on the average. There was a tendency for the eye to stop short of the correct point, but it occasionally went too far. The subject had no sensation of these defects of fixation. The average rates of reading of all types of matter were fairly constant for all subjects. They varied with the attitude of the subject towards the matter. When the subject was not attending to, or was completely uninterested in, the meaning of the content, reading was rapid and regular, with few regressions, and often increased in rate towards the end of the passage. When the subject was interested, and had some difficulty in comprehending the meaning, reading was slower, with large irregularities and numerous regressions. The greater the personal interest the slower the reading and the more irregular the regressions. Individual variations were thought to depend partly upon muscle balance of the ocular muscles, and partly upon acuity of vision and accuracy of refraction. Some of the subjects of the experiments suffered from ocular defects, but these were not investigated before experimentation. There would appear to be some value in correlating ocular defects and rate of reading and variations in fixation. It is evident that any defect that will affect these reactions will influence the onset of fatigue.

AUSTRALIAN ECONOMIC DEPRESSION

Owing to the world-wide downward movement in the prices of primary commodities (writes a correspondent) the value of Australian exports for the year 1929–30 was £40,000,000 less than for 1928–29. The cessation, moreover, of overseas loan flotations (by means of which Australian Governments for the preceding ten years had borrowed an average annual amount of almost £20,000,000) has been an additional factor in producing a drastic and relatively sudden reduction in the Australian national income. This reduction, falling, as it must, directly or indirectly, upon every member of the community, is affecting to an appreciable degree the position of the medical profession. Specialists, especially those treating chronic and less urgent conditions, have experienced a noticeable, and in some cases a considerable, reduction in the numbers of their private patients. For younger practitioners in such branches, moreover, the falling-off in well-established practices has been a source of some discouragement, at least as regards their immediate futures. The general practitioner, however, now that the first widespread family economies (consequent upon exaggerated fears of the "depression") have subsided, has not suffered to the same degree. The reduced earning power of the community is reflected rather mournfully, nevertheless, in an increase in bad debts, delayed payments, and temporary defaults. Economic depression, while producing no obvious diminution in the incidence of disease, has demonstrated very prettily how requests for a consultant, calls for a general practitioner, and, above all, visits to a specialist, are dependent to a considerable degree upon the income of the average individual and its

purchasing power, as regulated by price levels within the nation. The response of Australia to her changed circumstances has been general and complete. Rigid economy in expenditure, public and private, is everywhere the rule. Costs of production and distribution are falling. The cost of living has been reduced by 8 per cent. at least. Not only has Australia wrested from England the Ashes, but the more doubtful honour of paying the highest taxation per capita of any nation upon earth is now hers by right as well.

PITHEAD BATHS

In 1920 the Mining Industry Act was passed, and one of its provisions was the establishment of the Miners' Welfare Fund, from which grants were permitted for the erection of suitable baths and clothes-drying accommodation at the pithead. Six years later thirty-one schemes were in existence, accommodating 23,600 men. By the provisions of the Coal Mines Act of 1926, a 5 per cent. levy was imposed upon coal royalties, and as a result £200,000 was raised, which, added to £150,000 per annum contributed by the Miners' Welfare Committee, made a total of £350,000 available for the purpose. As a preliminary to the main programme of construction the Miners' Welfare Committee decided to make some experiments with four installations. Dr. Vernon and Dr. Bedford of the Industrial Health Research Board undertook the necessary research, and were engaged during the years 1927–29 in investigating the various problems encountered.[1] A summary of the findings discloses many interesting facts of physiological importance. In order to find the rate of drying of a bundle of wet clothes discarded by a miner coming up from the pit, damp towels were spread over small bundles of suspended clothes, and observations were made by means of the wet and dry bulb thermometer. It was found that the time required to dry the towels to a given extent varied inversely as the vapour tension difference. In certain circumstances it was inevitable that the overhead suspension system for clothes should be adopted in the baths, and here the best arrangement was that of gilled steam pipes 7 to 8 feet above the floor. This maintained a temperature of 13° F. above that of the room below, where the men were changing, and was infinitely superior to the method of smooth overhead steam pipes or of hot-water pipes. The latest type of bath has separate sections for clean clothes and for pit clothes, and all the garments are kept in lockers. This inevitably leads to a slower rate of drying than if the clothes are hung in the gangway outside, chiefly because the ventilation is poor, and the clothes may also press against the sides of the locker, causing a delay in drying. The best type of locker is that which has a central hook from which the clothes are hung. The ventilation of the new locker baths is carried on by extraction fans and roof ventilators; the air is admitted by gratings in the wall at a height of 2½ feet above the floor, and is slowly warmed as it passes in, but its rate of entry cannot be controlled. The roofing is of corrugated steel, covered with a thin layer of asbestos felt. Owing to the free transmission of heat the inside temperature of the building varies from 110° F. in summer to 40° F. in winter.

NEW YEAR HONOURS

The list of New Year honours, published in a special supplement to the *London Gazette*, includes the names of twenty or thirty members of the medical profession. A baronetcy is most fittingly conferred on Sir John Rose Bradford, K.C.M.G., F.R.S., consulting physician to University College Hospital, who has held with great distinction the office of President of the Royal College of Physicians of London since 1926. Lieut.-General Harold B. Fawcus, Director-General, Army Medical Services, is promoted K.C.B.; and Professor Ashley W. Mackintosh of Aberdeen, honorary physician to His Majesty's Household in Scotland, is appointed K.C.V.O. Dr. Jane Walker, pioneer in the open-air treatment of consumption in England, and founder of the East Anglian Sanatorium, of which she has been medical superintendent for the past thirty years, is created a Companion of Honour. Three medical men receive the honour of knighthood: Dr. Ernest Graham Little, physician in charge of the skin department of St. Mary's Hospital, and M.P. for the University of London; Dr. James Smith Whitaker, who was Medical Secretary of the British Medical Association from 1902 to 1911, when he became deputy chairman of the National Health Insurance Commission, and since 1919 has been a senior medical officer in the Ministry of Health; and Mr. Ambrose Edgar Woodall, surgical specialist to the Ministry of Pensions and surgeon to the Manor House Hospital. The C.B. is awarded to Major-General Lawrence Humphry, D.D.M.S., Western Command, India; and the C.B.E. to Dr. Agnes Catherine Scott, chief medical officer and secretary of the Dufferin Funds, Miss Louisa Martindale, surgeon to the New Sussex Hospital, Brighton, Mr. Ernest B. Waggett, D.S.O., consulting surgeon to the throat and ear department, Charing Cross Hospital, and Professor Sidney Russ, who has been in close touch with medicine as physicist to the Middlesex Hospital and as scientific secretary of the National Radium Commission. The peerage conferred on Sir Ernest Rutherford, immediate Past-President of the Royal Society, recognizes the work of an epoch maker in physics, and Sir Richard Gregory's baronetcy will be welcomed by all who are aware of what he has done to promote the physical and biological sciences during the past thirty-seven years as assistant editor and editor of *Nature*. A full list of the New Year medical honours will be published in our next issue.

Professor Ernst von Romberg of Munich informs us that the commission entrusted with the grant of the Dr. Sophie A. Nordhoff-Jung Cancer Prize for the best work of recent years in the field of cancer research has unanimously awarded this prize to Dr. Alexis Carrel of the Rockefeller Institute for Medical Research in New York, for his development of the method of tissue cultivation and his application of it in the solution of the basic problems of pathological growths, especially the growth of malignant tumours. The commission was composed of Professors Borst, Döderlein, von Romberg, and Sauerbruch.

The King has appointed Major-General H. P. W. Barrow, C.B., C.M.G., D.S.O. (Health Officer), to be an official member of the Executive Council of the Presidency of Antigua.

THEORIES OF THE BACTERIOPHAGE

PROFESSOR BORDET'S CROONIAN LECTURE

Professor Jules Bordet, foreign member of the Royal Society, delivered the Croonian Lecture at Burlington House on December 11th, 1930. The title of his lecture was "Les Théories des Bactériophages," but it was given in English. It will appear in full in the *Proceedings* of the Royal Society; the following is an abstract.

The phenomenon of the destruction of microbes known under the name of bacteriophagy, or transmissible autolysis, quickly aroused the liveliest interest. Is it not surprising that a bacterial culture grown on the surface of an agar medium becomes sprinkled with holes, in the neighbourhood of which the culture becomes deeply corroded? Is it not further remarkable to find that a broth to which has been added the active principle responsible for this effect is rendered unsuitable as a culture medium; or that under the action of the same principle a turbid microbial suspension obtained by emulsifying the culture from a solid medium becomes clear? Is it not even more remarkable that the active principle regenerates itself in producing its effect and can accordingly be reproduced indefinitely?

The active principle is frequently found in water, soil, and faecal materials, and vaccine lymph often contains a principle of this kind acting on the staphylococcus. It was soon recognized that there exists a number of these principles, distinguished from each other by the species of microbe which each has the power of attacking. One often finds, however, that the same active principle can attack several microbic species if these are sufficiently related. In particular, there exist principles acting on *Bacillus coli* which are also capable of affecting the dysentery bacillus. When a principle specific for one species of microbe is brought into contact with another species its lytic effect on the second species is usually increased with successive transmissions, but powers of adaptation are very variable. These principles are destroyed by heating to a temperature usually in the neighbourhood of 70° C.

If a tube of bouillon is inoculated with *Bacillus coli*, and a small dose of the lytic principle for this organism is added, agar tubes being subsequently inoculated with the mixture at given intervals of one or two hours, the first tube, inoculated immediately after the principle has been added, becomes covered with a normal layer of bacterial growth; the tube inoculated an hour later shows clear spots characteristic of lysis, and those inoculated after two, four, and six hours show greater numbers of clear spots. The lytic principle, therefore, multiplies itself in a culture of *Bacillus coli*. Moreover, cultures made from suspensions of *Bacillus coli* to which varying amounts of the principle have been added show a sprinkling of lytic spots, which are more numerous in proportion to the increasing amounts of lytic principle added to the suspensions. It was on these experiments that d'Herelle based his theory that the lysis produced by bacteriophage was due to a filter-passing virus which penetrated and destroyed the bacterium. The fact that when dilution of the principle is adequate the spots of lysis are isolated, is taken by him as an indication that the principle is present in corpuscular form and not in a state of solution. But the principle loses its activity at 70° C., and is probably a colloid, and therefore, in a sense, composed of particles, though this does not involve its being a virus. Whether it is a virus or not, it is certain that contact with bacteria sensitive to its action is necessary for its reproduction. Objections have been raised to the virus theory on the grounds of the resistance of the principle to storage and to the antiseptic effect of an equal volume of chloroform over long periods of time. If a weak dose of principle is added to bouillon which is then inoculated with a sensitive organism, growth is at first active, but lysis occurs four or five hours later with extraordinary suddenness. It is difficult to suppose that an intrabacterial virus, originally present in a small amount, at a given time attacks all the bacteria simultaneously. It has been shown by Doerr and Gruninger that under such conditions the quantity of principle increases while the bacteria are multiplying, and one cannot help thinking that this is favourable to the theory which I put forward ten years ago with Cinca—namely, that the bacterium secretes the lytic principle, and that bacteriophagy is autolysis. In order that the principle may be regenerated the bacteria must be both living and nourished, so that they are able to multiply.

In 1921 I observed with Cinca that a rabbit injected with a lysed bacterial suspension produces an antilytic serum which retains its activity when heated to 60° C., a temperature which spares antibodies and antitoxins, but which abolishes or reduces the bactericidal properties of serums. Moreover, for certain principles, the elimination of calcium suppresses lysis in bouillon and hinders regeneration of the principle, although the bacteria continue to develop; other principles are not adversely affected by calcium privation. It is permissible to suppose that all principles require some calcium for their action and reproduction, but that they do not all require the same dose of it. The impression which emerges from these considerations is not at all favourable to the hypothesis of an intrabacterial virus. I formulated a theory with Cinca in 1920 which is frankly opposed to that of d'Herelle, and which may be summarized as follows:

1. The invisible virus of d'Herelle does not exist. It is the bacteria themselves, subjected to the lysis, which produce the lytic principle. The case is one of autolysis.

2. Bacteriophagy represents the pathological exaggeration of a process which is physiological to bacteria, and is the result of a vitiation which has occurred in the accomplishment of a normal process.

3. This normal process may have some relation to the phenomena of mutation. A single bacterial strain may include several distinct types; an equilibrium is maintained between them by some regulator mechanism which evokes the idea of an antagonism between the different types. One may imagine that in certain circumstances their mutual reactions become considerably exaggerated and represent a cause of destruction among the bacteria.

There are difficulties to be surmounted before such a conception can rank with positive ideas based on facts. If one believes that the lytic principle is reproduced by the very bacteria which undergo lysis, one is forced to admit that the principle possesses the power of compelling the bacteria to fabricate a principle identical with itself. The theory implies further that the bacteria already contain the materials necessary for the formation of this principle. Though disconcerting at first, this idea appears to be quite plausible, and is comparable with the sequence of events found in the production of thrombin. Serozyme, one of the constituents of thrombin, exists in the plasma in the form of an inactive mother substance which I have called proserozyme. Thrombin has the power of transforming proserozyme into serozyme, ready to unite. At the beginning of the process, contact with some foreign body determines this transformation, but as soon as a certain dose of thrombin has been formed the contact is unnecessary, the thrombin itself producing an identical effect.

If one imagines that the physiological mechanism which presides over mutations is the primary cause leading to the appearance of lytic principles, it is to be presumed: (*a*) that the effects produced by the bacteriophagic

principles will have some relation to the phenomena of mutation, and that (*b*) in studying the behaviour to one another of different types occurring in normal cultures one will be able to determine that these types manifest antagonism to one another, revealing itself by lytic phenomena analogous to bacteriophagy.

Let us take the case of the bacteriophage which is active towards *Bacillus coli*. I had early observed that if one adds to an extremely weak dose of this principle an enormous quantity of *Bacillus coli* the principle disappears. This result is not favourable to the virus theory; it would be difficult to suppose that a parasite would disappear when presented to too great a quantity of the bacteria which it is in the habit of attacking. If a slightly larger dose of principle is added to the same quantity of bacteria it reproduces itself, but is no longer identical with the original principle; it may be described as "weak principle" in the sense that it produces incomplete lysis of cultures of *Bacillus coli*. This weak principle may also be obtained by introducing into a tube of bouillon, to which has been given a large inoculation of *Bacillus coli*, a moderately large dose of the initial principle, and by not allowing it to act on the organisms for more than a very short time. If the experiment is so planned, the principle acts exclusively on the most sensitive of the organisms, and these regenerate a lytic agent which is so exclusively adapted to them that it will no longer produce any effect except on microbes of an identical character; so that when mixed with a complete culture it only produces a partial lysis. Thus the individuality of a given type of organism is reflected in the qualities of the principle which it is capable of elaborating.

Thanks to Dr. Arkwright, it has been established that cultures of *Bacillus coli* tend to split into two well-defined types. Certain colonies are convex and smooth ("smooth" type) and others are flat and wrinkled ("rough" type). In bouillon the smooth type produces uniform turbidity, the rough type floccules in a clear fluid. The smooth type, especially in bouillon, tends soon to give rise to the rough type; and the rough type, though more stable, tends eventually to produce a few individuals of the smooth type. The weak principle attacks the smooth type by preference, while the rough type resists it; if a drop of the weak principle is added to a culture of the smooth type, lysis occurs, but after a few hours a luxuriant growth of the rough type appears, arising from the few individuals of the rough type which the smooth culture had a tendency to produce. Is it not plausible to think that the weak principle might represent a more active form of a substance which the smooth type would normally produce, and which would have the power of making the rough type appear at its expense?

By transferring large doses of weak principle and organisms in the process of lysis from one tube of fresh bouillon to another the principle gradually acquires the power of attacking the rough strain. The principle thus adapted attacks both the smooth and the rough type, and deserves the name of "strong principle." Both principles would appear to exist in the bacteriophage which normally attacks *Bacillus coli*. If it has been demonstrated that the weak principle can become the strong principle, may not the weak principle be derived from a principle still weaker, which might be precisely the normal and physiological substance responsible for the appearance of the rough at the expense of the smooth strain?

If a small droplet of weak principle is allowed to run down the middle of an agar slope which has previously been spread with a culture of the smooth strain over its whole surface, a clear strip of lysis appears down the centre, while the culture develops normally on either side. In the strip where lysis has occurred some colonies of the rough type soon appear, but, in addition, the layer of microbes contiguous to the clear strip takes on a special appearance. It becomes slightly transparent, so that the strip is surrounded by a visible halo. Sertik, a partisan of the virus theory, supposes that, while multiplying, the virus liberates an enzyme, which diffuses into the neighbouring zone and produces a partial lysis. So far as concerns the haloes I have observed, I think that they reveal, not a dissolution of the microbes, but an influence which tends to confer on those of the smooth type the characters of the rough type. Examined by transillumination with artificial light the unaffected part of the culture is iridescent, after the usual manner of the smooth type, while the halo is dull and greyish after the manner of the rough type. Commonly, the halo disappears at the end of two days, the organisms which compose it not having been impressed with the energy required for their definitive modification. For this reason, when one inoculates them into a new medium one often obtains a culture of the normal strain. The power of producing a halo belongs only to the weak principle, the principle characterized by a tendency to transform the smooth strain into the rough; moreover, one finds that the halo owes its visibility to the fact that in this region the smooth culture takes on the aspect of the rough, as though this metamorphosis were beginning to be accomplished. The strong principle does not produce a halo.

The result of my most recent experiments, carried out with Renaux, emphasizes these details. It is generally admitted that lytic principles do not produce any perceptible effect on dead organisms. But we have observed that the weak principle introduced into a suspension of *Bacillus coli* of the smooth strain, whether dead or alive, causes a strong agglutination even in minimal doses. The strong principle does not produce this effect. If one takes account of the fact that the smooth type clouds bouillon uniformly, while the rough undergoes spontaneous agglutination, it is interesting to find that the weak principle, which brings about the metamorphosis of smooth to rough, is the one which is endowed with the power of agglutinating organisms of the smooth type, even when they have been killed. It is probable that the weak principle, to which the rough type is resistant, does not agglutinate the killed organisms of this strain, but it is difficult to determine, in view of the fact that these organisms undergo spontaneous agglutination. The foregoing facts entitle us to consider that the effects of the lytic principles have a connexion with the phenomena of mutations.

The other question raised was as follows: Do the different types of microbes belonging to a single species manifest an antagonism to one another which can be revealed by the phenomena of lysis? Lisbonne and Carrère in 1922 showed that different strains of *Bacillus coli* bring about lysis of dysentery bacilli when cultivated with them in bouillon; moreover, the filtrate of such a culture causes a lysis of dysentery bacilli which can be transmitted in series. In 1923 I was able to transfer this conception of antagonism into the framework of one and the same species, showing that bacteriophagy really enters the domain of normal physiology. By submitting to the process of isolation an initial culture, of which the behaviour in other respects seems perfectly normal, one can extract from it strains which are clearly antagonistic. Certain of them exercise on certain others a lytic action, which is thenceforward transmissible, and one can say that some behave as aggressors and others as recipients. Further, a particular germ whose secretions are aggressive, or lytic, for certain members of its family, may be receptive to the lytic secretions of

different members. One is brought to believe that the total population of a culture of a microbe is the seat of perpetual inter-reactions between the individuals which compose it. One may suppose that the lytic power represents a regulative influence. To summarize, in *Bacillus coli* and staphylococcus, which are the species I have had under consideration, one can detect the existence of a spontaneous lysogenic power, provided that, having separated the different strains, one brings the most aggressive into contact with the most receptive in such a way as to allow lysis to be sufficiently intense to show itself clearly. There are some species—for example, the *Bacillus pyocyaneus*—in which the antagonism of different strains may be so pronounced that clear spots of spontaneous lysis readily appear in their cultures. One can demonstrate that at the site of these clear spots a conflict is in progress between distinct types; repeated reinoculation from such spots can furnish a new race of the organism, easily distinguished from the original strain.

Partisans of the virus theory assume that the virus may frequently live in symbiosis with the bacteria without causing visible lysis. But in spite of repeated isolations one does not succeed in depriving lysogenic colon bacilli of their aptitude for starting lysis of the dysentery bacillus. It would be necessary to assume that each individual organism, which at the time of its isolation gave rise to a colony otherwise normal, was infected by the virus. Since the principles which these colonies furnish are not identical, it would be necessary to admit, further, that the virus can diversify itself into many unequally active races. Finally, considering the metamorphosis of the smooth into the rough type caused by the weak principle, would it not be strange that a virus should favour a mutation which can be accomplished without it, and which is, in reality, a physiological process? Is it not more rational to think that the virus does not exist, that the action of the bacteriophage represents the pathological exaggeration of a normal function connected with mutations, and that this lysis is, in fact, a transmissible autolysis?

SILICOSIS IN SOUTH AFRICA

REPORT OF THE MINERS' PHTHISIS BUREAU

The report on the year's work of the Miners' Phthisis Bureau[1] by the chairman, Dr. Louis G. Irvine, contains a mass of information, and is a record of which any organization might well be proud. The numbers and extent of the routine examinations carried out by the members of the bureau and the pathologists of the South African Institute for Medical Research are evidence of the thoroughness with which the responsible authorities deal with the medical problems associated with the Rand gold mining industry. Upwards of 46,000 clinical and 24,000 pathological examinations were made during the year on some 30,000 individuals, while 42,000 portrait negatives of miners were produced for purposes of identification, and 35,000 radiographs were taken. The enormous number of radiographs in the possession of the bureau has become a serious embarrassment, not only because the films have to be stored in such a way as to permit of easy access for reference, but also because of their inflammable nature. It is hoped that in the near future it will be possible to make such arrangements that the risk from fire will be reduced to a minimum, while the usefulness of the collection will be unimpaired. The bureau lays great stress on radiography in the diagnosis of pulmonary lesions, but it is fully alive to the danger that the interpretation of very large numbers of *x*-ray pictures may become a matter of convention unless they are controlled from time to time by careful post-mortem observations. There is very close co-operation between the clinicians, the radiographers, and the pathologists. Whenever possible the clinical and *x*-ray findings are compared with the actual lesions revealed at necropsy, and a considerable series of cases has already been collected illustrating the value of this correlation.

The chief importance of these annual reports lies in the fact that they record year by year the progress of the fight against silicosis, and indicate how far the preventive measures against dust in the mines are successful. On July 31st, 1929, the bureau possessed medical and radiographic records of 76,281 European miners, but the statistical analysis of these data is extremely difficult, for there are so many complicating factors. It would, for example, be manifestly unfair to regard every case of miners' phthisis arising on the Rand as due to the industrial conditions obtaining there unless it was certain that the miner had not been employed in dusty occupations elsewhere. Again, tuberculosis is the chief danger to be feared in dusty occupations, but dust is not the only factor which determines the onset of phthisis; the physical condition of the individual is also important, and should be ascertained before he becomes a miner. Previous to 1916 intending miners were not examined medically, and no note was taken of their previous industrial history; since that date every man who desires to take up work in the mines has to pass a rigorous "initial examination" as to his general fitness for underground work. In 1928–29 7,737 Europeans, including those of South African birth, were examined in this way, and 15.54 per cent. were permanently rejected; 45.51 per cent. were temporarily rejected, which means that they were found to have defects of health and physique which the examiners considered remediable. Many of such candidates eventually succeed in obtaining an initial certificate. These "new Rand miners" who have only worked in scheduled mines since August 1st, 1916, now form rather more than half of the total number of working miners, and it is from the analysis of the data derived from these men that the most reliable information may be expected. It would seem, however, that it is too early yet to come to very definite conclusions as to the incidence of silicosis among the new Rand miners, for comparatively few of them have worked for long periods underground, and time is an important factor in the incidence of the disease. Some 25 per cent. of those who enter underground work appear to relinquish it after a year's trial; in the fifth year only about 50 per cent. remain, and in 1929 only 473 had worked for over ten years.

The total number of cases of simple silicosis among all the new miners employed since 1916 is only fifty-two, but there appears to be some evidence that the incidence rate is increasing with the length of service; thus eleven cases were discovered in the periodical examination of 7,231 new miners in 1927–28, while twenty-two cases were discovered in 8,360 men in 1928–29. But whereas the average duration of underground service of the new silicotics in 1919–20 was 114 months, in 1928–29 it had increased to 151 months, which suggests that the preventive measures adopted against underground dust are bearing fruit.

An interesting section of the report deals with the subsequent history of new cases of simple silicosis. It appears to be quite clear that uncomplicated silicosis may undergo prolonged, sometimes apparently indefinite, arrest for long periods of time, but many of the cases tend to progress from the earliest detectable stage, the anteprimary stage, to a much more advanced fibrosis. Thus out of 219 new cases detected in 1920–21 156 were

[1] Report of the Miners' Phthisis Medical Bureau for the Year ended July 31st, 1929. The Government Printer, Pretoria. 1930. (3s. 6d.)

living at the end of the eighth year—52 had remained stationary, but 104 had advanced to the primary or the secondary stage. In the classification adopted on the Rand secondary silicosis includes tuberculosis, and it is pointed out that 75 per cent. of the deaths which occur in silicotic miners are due directly to active tuberculosis.

Dr. Irvine suggests that there exists in many, if not most, of the cases of clinically "simple silicosis" from the earliest stages a latent element of low-grade tuberculous infection, and he regards the presence of such latent foci as a partial explanation of the tendency manifest in so many cases of simple silicosis to the ultimate development of active tuberculosis. Whatever the explanation may be, it is undoubtedly true that in recent years there has been a change in the prevalent type of silicosis in the direction of an increase in the relative importance of the infective factor in the course of the cases which have arisen. There are, of course, other possibilities, and these are clearly indicated and critically discussed. Dr. Irvine is to be congratulated on the lucidity with which he has set forth a wealth of very complicated and difficult statistical material. The bureau reports deal with conditions which exist nowhere else, and no student of tuberculosis or industrial medicine can afford to neglect them.

Scotland

Health of Scottish Workers

Sir Thomas Legge, M.D., formerly senior medical inspector of factories, delivered a lecture on December 10th, 1930, to the Edinburgh Women Citizens' Association in which he dealt with the safeguarding of workers, with special reference to women. In describing the struggle that had been waged in his department against lead poisoning and other diseases found among workers in such industries as pottery making and house painting, he pointed out that great improvements had been effected by legislation and by the introduction of automatic machinery. Poisoning, for example, from motor car painting had been reduced by a new process of cellulose spraying, and exhaust ventilation had counteracted to some extent the danger to young women working in potteries and aeroplane factories. The ventilating fan, in his opinion, was the principal means for protecting the worker. Factory conditions to-day, he said, compared very favourably with those prevailing in the first half of the nineteenth century. At that time child workers of seven years of age laboured fourteen and a half hours daily for half a crown a week, while an overlooker superintended them with a strap.

At a conference on industrial maladies held in Glasgow on the following day, under the auspices of the Scottish Trades Union Congress, Sir Thomas Legge delivered an address on the past and future work of the trade unions in the prevention of these diseases. Trade unions, he said, had succeeded the mediaeval trade guilds and had originated as a protest against a number of abuses incident to the industrial revolution, including long hours, exploitation of child labour, and occupational diseases. Injury from noxious substances was still widespread, but their effects could be greatly alleviated and even abolished. Phossy jaw, for instance, which used to be a terrible disease among match workers, was now of historic interest only, owing to the substitution of a harmless phosphorus compound for the old fuming yellow phosphorus. Prevention of disease depended largely upon methods over which the workman had no control, such as disinfection of wool and horsehair carrying anthrax; installation of machinery for blowing and moulding glass, and exhaust ventilation for protection in dusty processes. Everything, however, depended upon the efficiency with which these methods were carried out. Silicosis was an incapacitating disease among stone masons, grinders of cutlery, pottery workers, and among miners drilling through stone, but a safeguard had been found in utilizing compressed air to trap the dust and prevent its inhalation. Trade union officials had been the first to call attention to the skin irritation, sometimes followed by cancer, caused by tar among briquette makers in tar distilleries and in gasworks. Much had been done to keep this in check by effective medical supervision. Skin troubles were still excessively common, such as bakers' eczema, chrome ulceration in the manufacture of bichromates and in the new process of chromium plating for motor car and bath fittings. It was the duty of employers to take the necessary steps to minimize these troubles.

New Glasgow University Union

The new Students' Union for Glasgow University, which has cost about £60,000, was opened on December 12th, 1930, by Mr. Stanley Baldwin, Rector of the University. The old Union building is to be handed over to the University authorities for use as administrative offices Mr. R. M. Minto, president of the Union, presided, and Mr. Baldwin was accompanied by Sir Donald MacAlister, Chancellor of the University, and by Principal Rait. In welcoming Mr. Baldwin, Sir Donald said that £122,000 had been received as the result of an appeal that had been issued by him in the name of the Students' Welfare Committee about nine years ago. Part of this sum had been expended on the new buildings. The Rector said that he was very keen about university life all over the country, because he thought that the universities held the key to our civilization. He regarded such a Students' Union as an absolute necessity in Scottish universities, as it was the only means the students had of completing their university education. There were two kinds of education, he said—namely, the process of acquiring knowledge, and, equally important, the education that was obtained by social intercourse. It was the latter kind of education that enabled students to take their part in the life of the community. The number of university men who devoted their subsequent lives to study and tuition was comparatively small, and even they would be twice as long in finding their feet in the world without some form of social discipline. He hoped that the new Union would become a wider centre than the old, and that debates would be carried on with the customary vigour. He had no fear for the future of Glasgow men, and he would watch their careers all over the world as long as he was privileged to do so.

The Mental Factor in Disease

In a recent address on the mental cure of disease, delivered in Edinburgh, under the auspices of the Combe Trust, Dr. F. K. Kerr suggested that the enormous amount of public interest taken in health matters since the war could be accounted for largely by the fact that only three out of every nine recruits under the Derby scheme had been found to be fit for front line duties. About 33 per cent. were in category C 3, and these were still with us. In the lower animals the body was everything, but in man the body was an annexe to the mind. Complicated actions of everyday occurrence, like walking, opening a door, shaving, and so forth, could be performed while the mind was otherwise occupied. As soon as disease appeared, the imagination was aroused; a cut finger, for example, conjured up lockjaw, a headache meningitis, a bad cold pneumonia, a vague pain cancer, and so forth. This was a great natural provision for the preservation of health, which, however, was adversely affected by fear stimulated by ignorance. There was far too much talk about disease and not enough about health.

Suggestion by talk about disease might predispose the mind to illness and aggravate the illness when it occurred. The proper attitude towards disease should be built up beforehand by inculcating a disease philosophy; disease should be accepted like the weather. The mental cure of disease was most successful when carried out unconsciously. Assurance that inspired confidence, and simple explanation, were the main forces in effecting a cure. The people of this country were suffering from an inferiority complex, a bad reaction from jingling jingoism. The old ideal must be reached again by building up a healthy nervous system in the individual, but good housing, good food, an interest in work, and a prospect beyond the material standards were essential. The ordinary working man of about 40 years of age had bad teeth and an unhealthy throat. He lived in an insanitary house, and worked monotonously in a draughty shop every day. For his breakfast he had a foreign egg out of cold storage, bacon from America, bread from American flour devitalized by chemicals, and he washed all this down with a small bucket of stewed tea. His other meals were no better. The handicaps to health were bad housing, bad dieting, bad cooking, too much clothing, lack of exercise and games, and lack of intellectual interest among the artisan class.

Glasgow Western Infirmary

At the annual meeting of the Western Infirmary, Glasgow, held on December 23rd, 1930, Colonel J. A. Roxburgh, LL.D., chairman of the board of governors, intimated that during the past year the number of patients had been larger than in any year since the institution was opened in 1874. Patients treated for motor accidents alone numbered 659; of these, 281 were in-patients, with an average stay of nineteen days. It was interesting to note that 191 of these in-patients were pedestrians. In this connexion some relief might be expected from the Road Traffic Act, 1930, which provided that in the case of a person meeting with a motor accident and receiving treatment in a hospital there should be paid by the authorized insurer or owner the expenses reasonably incurred by the hospital to an amount not exceeding £25 for each person treated. During the year the beds in the David Elder Infirmary at Govan, under the management of the Western Infirmary, had been fully occupied, 655 cases having been treated. An experiment was about to be made for a year in that institution with a ward, containing seven cubicles, for the use of those patients who, while unable to pay for treatment in a nursing home, were willing to contribute towards their maintenance in the hospital. In referring to the new radiology department, described in the *British Medical Journal* of November 1st, 1930 (p. 753), the chairman said that in the course of the year the Western Infirmary had been selected by the Radium Commission as the radium centre for Glasgow. An ample supply of radium was available, and arrangements had been made to take the fullest advantage of the opportunity. The school of nursing and the school of massage continued to maintain their high standard of efficiency, and the appointment of nurses to prominent posts at home and abroad testified to the success of the training they received at the Infirmary. More than 7,000 nurses participated in the federated superannuation scheme, which had been adopted by 380 institutions with over 40,000 beds. These figures represented 56 per cent. of the total voluntary bed complement in Great Britain, and 75 per cent. of all the institutions having 200 beds and over. A review of the financial position for the year seemed to indicate that the ordinary income would be similar to that of the previous year. Extraordinary receipts, however, including legacies, were larger than usual

England and Wales

Arrangements at London Council Hospitals

The first nine months' working of the Local Government Act by the Central Public Health Committee of London can be said to have been smooth and successful. A very large number of rearrangements have been made at the various transferred hospitals. One step recently taken is to " appropriate " for the purpose of the reception of the sick, under the powers given by Section 14 of the Local Government Act, the twenty-eight general hospitals and certain children's hospitals and convalescent homes under the control of the London County Council. The advantages of appropriation are that these hospitals will be removed from the Poor Law, and consequently from the operation of the Public Assistance Order, 1930; that patients other than those ordinarily described as destitute can be admitted for treatment, though the Council's duty to provide relief for the poor still remains a statutory obligation; and that the Council itself will be able to prescribe the duties of the medical superintendents and principal officers. At certain of the Council's general hospitals laboratories have been established to serve the purpose of a group of adjacent institutions. The group laboratory at Lambeth Hospital is expected to be ready in April next, that at the Holborn and Finsbury Hospital (now called Archway Hospital) in the summer, and those at St. Mary Abbots and Hackney Hospitals before the end of the year. Out of the twenty-eight general hospitals under the Council's control, pathological work is undertaken already at ten to a varying extent, and four of these will serve as group laboratories. At the other eighteen there is little or no laboratory work, but laboratory facilities in adapted premises are to be provided at nine of them as soon as possible. When all the laboratories at present contemplated are in operation very little pathological work will need to be sent outside, since hospitals without laboratories will avail themselves of the facilities at other council hospitals. The expenditure proposed for 1931–32 on laboratory provision is £18,750. This includes the adaptation and equipment of buildings, provision of staff, and maintenance. It is estimated that the average for subsequent years will be £13,750, apart from the provision of certain further laboratory staff, which will be necessary at a later date.

Hours of Sleep in Hospitals.

One question which has been exercising the Central Public Health Committee is the hours for sleep of patients in its hospitals. Under the boards of guardians the times of wakening of patients in Poor Law hospitals ranged from 5 to 7.30 a.m. The practice in the voluntary hospitals has been inquired into, and it appears from statistics gathered from sixty-three provincial general hospitals that in forty-five of these work begins before 6 a.m., and in the remaining eighteen at that hour or later. The authorities who favour retention of the present system of early wakening justify their preference by saying that there is no hardship in the present arrangement, that a later hour would not allow of a sufficient interval between the time at which the work starts and the hour fixed for the visits of the medical staff, and that in any case most of the patients are accustomed to early rising. It is held that there must be conformity of other arrangements to the hour at which the medical staff commence their rounds, usually about 10 a.m., and the time necessary to prepare patients and wards for the medical officers' visit must be governed by the staff available. In turn, the hour of wakening regulates the hour for closing down in order to ensure that the patients have sufficient rest. In the Council's hospitals the patients are rarely disturbed after

8 p.m., and nine or ten hours are therefore available for rest. At the Middlesex Hospital, which has recently instituted the practice of allowing its patients to sleep until 7 a.m., it is pointed out that there are fourteen nurses to forty beds, and an overlapping of day and night nurses of more than half an hour. In none of the Council's hospitals does the nursing staff approach the proportions of that of the Middlesex Hospital; at present there is a shortage of nursing staff, though the position is being gradually improved. It is proposed that, as far as practicable, no patient shall be wakened, except in special circumstances, before 6 a.m. The process of rising to this standard must necessarily be gradual, and preferably should take place in one hospital and one ward at a time. It is intended to consider the matter further after twelve months in the light of information then available.

Birmingham Hospitals Centre

A memorandum on the Birmingham Hospitals Centre by Sir Charles Grant Robertson, chairman of the executive board, reviews the work accomplished in 1930, and explains various features of the scheme about which there appears to have been some misunderstanding. The first practical step, after three years' preparation, was undertaken in the summer of 1929, by arranging a public competition of leading hospital architects. The award was approved at the beginning of last year, the winning design being that of Messrs. Lanchester and Lodge of London. Meanwhile an appeal committee had been set up, and a public appeal for funds was launched at a meeting held in April. Since that date, the committee has succeeded in raising £584,000 of the £1,250,000, which is approximately the estimated cost of the scheme. The result to date is considered to be very satisfactory. The Birmingham Hospitals Centre, which was incorporated by licence on June 13th, 1930, is now a legally constituted body, of which the executive board is the central organ. The object of incorporation was to ensure that every penny placed at the disposal of the board would be available only for the defined purposes of the centre, which is governed by the law applying to companies not working for profit. In referring to the voluntary basis of the scheme and to the fact that it originated from the necessity of extending the General Hospital and the Queen's Hospital, the memorandum points out that since the executive board came into existence it was considered that the centre, as contemplated, would affect other voluntary hospitals in Birmingham—mainly concerned with specialized branches of medical science and treatment—and that any final scheme should take into account future as well as immediate requirements. Hence the board, before incorporation, included among its members representatives of these special hospitals, who will be able to take part in deciding the principal questions of policy and those in which they have a particular interest. Birmingham now possesses in the executive board a central body linking up the common interests of all the voluntary hospitals, through which, with due regard to the needs of special institutions, a common policy can be framed and gradually carried out. Besides appointing a consulting engineer to work with the architect in the preparation of the scheme, the board has set up three subcommittees to deal with the planning of (*a*) the nurses' home and services, (*b*) the surgical blocks, and (*c*) the medical blocks. Good progress is reported to have been made in each department, and other subcommittees will shortly be appointed to deal with other parts of the hospital design. In regard to the University section three professors of the medical faculty are visiting the United States, as guests of the Rockefeller Foundation, to study the arrangements of the newest and most important medical schools. While the capital for the medical school will be provided out of the public appeal fund to the extent of one-sixth, it will remain an integral part of the University, which will continue to be financially responsible for the staffing and upkeep of the medical school as planned, and will provide all the technical and scientific services on a larger scale and in a more efficient manner. The memorandum discusses at some length the essential relation between a teaching hospital and a medical school, and concludes by expressing the hope that the progress of this pioneer enterprise will not be hampered by lack of support during 1931.

Remuneration of District Medical Officers

The remuneration of district medical officers in London was fixed before the war, and has been subject to certain temporary increases authorized from year to year since 1918. The London County Council now proposes to consolidate the fees on a permanent basis. The new fees will be as follows:

For attendance, including all requisite medicines and simple surgical dressings, together with such certificates as may be required, 11s. 6d. a year for each employee; for certificates for persons not allowed medical attendance by the council, 3s. for each certificate, or, if a visit to the home of the employee is involved, 6s. for each certificate; for each certificate given under the regulation relating to suspected infectious disease in common lodging houses, 8s.; for each certificate given under the Children's Act, 1908, relating to nurse infants, 12s.; for each attendance when called on emergency to a fireman on duty in, but resident outside, the medical officer's district, 5s., if the fireman resides outside the administrative county of London, but no payment if the fireman is resident within the county.

These fees represent the merging of the additions authorized since the war with the amounts previously prescribed. It is laid down that the minimum amount payable to each district medical officer shall be at the rate of £25 a year.

Ireland

Treatment of Fractures

At the December meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, with the president, Mr. R. Atkinson Stoney, in the chair, Dr. Lorenz Bohler of Vienna gave an address on the treatment of fractures. He showed four cinematograph films, illustrating the methods of reduction and fixation employed in fractures of the shaft of the femur, fractures of the leg, and fractures of the forearm and fingers, demonstrating the use of local anaesthesia, of the unpadded plaster case, and of zinc gelatin paste. He also showed numerous lantern slides and radiograms, illustrating end-results. A vote of thanks to Dr. Bohler was proposed by the president, and was carried with great enthusiasm.

Vital Statistics for Northern Ireland

The Registrar-General for Northern Ireland has just published his eighth annual report on the marriages, births, and deaths registered during the year 1929.[1] This volume contains much useful information for those interested in problems relating to public health. As in 1928, the marriage rate in Northern Ireland increased slightly, but the birth rate continued to fall steadily, and was the lowest recorded for Northern Ireland in recent history. The death rate showed a sharp rise, due largely to deaths from influenza, bronchitis, and pneumonia in the first quarter of the year. The deaths from influenza increased from 388 in 1928 to 1,335 in 1929. The number of deaths

[1] H.M. Stationery Office, 15, Donegall Square West, Belfast, or through any bookseller. (2s. 6d. net.)

from tuberculosis has declined more or less steadily from over 3,000 per annum in 1917 and 1918 to 1,611 in 1929, which is the smallest number yet recorded for Northern Ireland. A salient feature of the deaths from tuberculosis is the high rate at certain ages; of the deaths between the ages of 15 and 25 from all causes more than half are due to tuberculous disease. The deaths from cancer numbered 1,469, a slight increase on the figure for 1928. The recorded rate from this cause has increased gradually over the past ten years in Northern Ireland. Of the total deaths, numbering 19,822, over 50 per cent. were attributed to the following diseases:

Heart disease	2,782
Tuberculosis	1,611
Pneumonia	1,486
Cancer	1,439
Bronchitis	1,248
Influenza	1,335
Cerebral haemorrhage	1,055

Deaths of infants under 1 year of age numbered 2,174 in 1929, of which 903 were due to congenital malformation, debility, and premature birth. The deaths ascribed to encephalitis lethargica numbered 37. Tables are included in the report showing deaths at different age periods under 205 separate causes, and the deaths under the principal causes for every rural and urban district in Northern Ireland. The number of deaths registered as uncertified, due to the fact that no medical attendant was present during the last illness, was 1,903 in 1929, an increase of over 100 on the number in 1928.

Correspondence

THE MEDICAL CHARITIES

SIR,—Members will shortly receive the Association's form of application for their annual subscription. Below the printed figure there appears a formidable list of objects for which subscriptions are invited; but so perplexing is the problem often found that the harassed practitioner seems generally to ignore it completely. But if he realizes that his donation, placed in Column 5, will be allocated by a careful committee, he need take no further trouble; £1 from each member would raise the medical charities from penury to affluence.

It has recently been brought home to me that the bulk of the profession fail to realize the need and the needs of our two splendid charities—the Royal Medical Benevolent Fund and Epsom College. That only 4,000 out of our 40,000 feel constrained to give either encouragement or aid can hardly be from any other cause. Ninety per cent. of us give nothing whatever, while the support of the 10 per cent. who do give (in subscriptions varying from 2s. 6d. to £100) quite fails to meet the needs.

One hears it said: "Why don't these people insure?" Many, perhaps most, do. But what is, say, £2,000 to a widow suddenly left with a family to feed, clothe, educate? And what is the financial result of an "accident" or "sickness" policy to a man suddenly and permanently struck down by trauma, encephalitis, or cerebral lesion? And what, again, is the proportion of our members who can contemplate with equanimity disasters such as these? And yet there is an annual average toll from which none of us are immune.

A moderate but universal support of these charities would constitute an insurance fund which, while helping those who have fallen by the way, would also relieve anxiety in many minds.—I am, etc.,

Tunbridge Wells, Dec. 29th, 1930. CLAUDE WILSON.

OBSTETRICAL EDUCATION OF THE UNDERGRADUATE

SIR,—In the report of the meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, published in the *Journal* of December 20th, 1930 (p. 1046), mention is made of the fact that I have discussed elsewhere the question of the education of the undergraduate. Unfortunately I was prevented from attending this meeting, but the scheme of clinical training outlined in the Departmental Committee's report corresponds very closely with that introduced in Glasgow University two years ago, except that we carry through the training in three months. We are satisfied that the undergraduate gains in these months a wide clinical experience; but we very much doubt if we could keep up his interest if this training were extended to six months. It must be remembered that obstetrics and gynaecology is a limited subject until taken up as a specialty. I am inclined to think that some obstetric teachers are losing a sense of proportion in insisting on a six months' whole-time training, and they are influenced in this by the fact that many of the smaller maternity units of the general hospitals in London have not adequate clinical material. But why should the student be penalized? Asking for six months to be devoted exclusively to obstetrics and gynaecology means a demand for 13 per cent. of the whole curriculum. Now Sweden, which has the longest curriculum of any country—namely, eight to nine years—only demands four months, or 5 per cent. of the curriculum. I maintain that if we have three months' whole-time training, this is all that is necessary for the undergraduate. We should in this three months' teaching of the undergraduate concentrate on ante-natal work. Three or four cases "personally conducted" in hospital and ten in the district, if the student is most carefully supervised, are quite sufficient.

All will admit that with the extended training which the Departmental Committee suggests, the young graduate will be a safer accoucheur than were his predecessors when they obtained a degree to practise medicine; but even with this or an infinitely more extended training he would not be competent to deal with the ordinary but serious problems in practical obstetrics, because he cannot be given opportunities during his training to perform operations or to deal with even ordinary complications of parturition (persistent occipito-posterior positions, post-partum haemorrhage, placenta praevia, prolapse of the cord, incomplete abortion, etc.). The public is aware of this, and trusts the staffs of all teaching hospitals that this principle will be respected. Of what profit is it to insist on medical students "personally conducting" thirty normal cases, as the Departmental Committee recommends, or even a hundred cases? It is not the number of cases personally conducted, it is the degree and quality of the supervision, that is the essential factor. Fifteen conducted under special supervision would be infinitely better than a hundred under little supervision.

Furthermore, as regards industrial areas, the midwives attend the normal cases. The doctors of the locality are called upon to treat the complications of parturition. A young graduate, in the capacity of partner, assistant, or locumtenent, may be faced with an ordinary but serious condition which he has never treated, and even with the extended training proposed he may not have seen treated, for in the smaller schools, where the clinical material is scanty in amount or widely distributed, only a few complications may have actually occurred during his period of training. The public is deeply interested in the subject of maternal and infantile mortality and morbidity. It has been told that matters are far from satisfactory, and it trusts the medical profession to correct existing conditions. It is unfair, therefore, to let it believe that an

extended undergraduate training is the method of solving that part of the problem concerned more especially with providing women in labour with medical practitioners adequately trained and able to deal with the serious but quite ordinary complications of obstetric practice. A term of "internship," with instruction and practice under obstetric surgeons, is the only method by which a safe accoucheur can be trained. The objection to establishing the full period of "internship" prior to graduation is that such pupils could not be given the responsibility enjoyed by qualified house-surgeons. I would make the suggestion that a year's "internship" for surgery, medicine, and obstetrics should be made compulsory after graduation. The suggested arrangement is as follows: the undergraduate, when he passes the final examination as at present constituted, or modified, should receive his degree or qualification, but his name would not be put on the *Register* until he has done a year's "internship." These qualified "interns" would take the place of the present house-surgeons and house-physicians, have residence and board in hospitals, but receive no salary. They would be distributed over the important hospitals of the country. The taking over of the Poor Law hospitals by the health authorities, and the additional hospitals which almost of necessity will have to be erected, would accommodate them. Many hospitals are experiencing great difficulty in securing house-surgeons, even when relatively high salaries are offered. A considerable economy could be effected if qualified "interns" took the place of salaried house-surgeons in large general and maternity hospitals throughout the country.—I am, etc.,

Glasgow, Dec. 20th, 1930. J. M. MUNRO KERR.

THE HAEMORRHAGIC DIATHESIS

SIR,—The object of this letter is to draw the attention of your readers to the possible value of liver feeding in cases of thrombopenic purpura, which Dr. Tidy does not mention in his address, published in the *Journal* of December 27th, 1930.

Some eighteen months ago Dr. Clapperton of Oakham had under his care a case of this variety of purpura of moderately severe grade, with considerable oozing from the gums, as well as ecchymoses. We discussed the advisability of splenectomy, but decided to give a trial to liver feeding. This was followed by a rapid improvement and a satisfactory cure, so that the patient, a young farmer, has been at work ever since.

I have tried the treatment in several cases of leukaemic purpura, but, as one would expect, with no effect whatever. I have not had an opportunity of trying it in Henoch's purpura. Its value in haemophilia has been demonstrated by Dr. Pickering.—I am, etc.,

Nottingham, Dec. 27th, 1930. F. H. JACOB.

AMIDOPYRIN IN MEASLES

SIR,—In common with others, having seen Loewenthal's article in 1924, I decided that amidopyrin should be tried in the next epidemic of measles under my care. The opportunity occurred in January, 1930, during an epidemic of 122 cases at this school. The results appeared inconclusive so far as the claim for its specific action, and for this reason did not appear worth recording. As, however, further evidence for and against has appeared since, this record may be of some interest.

The epidemic began in January with two cases, both boys being holiday infections. The second batch began on February 9th, and the epidemic continued until March 5th, 122 boys out of a total of 185 non-immunes being infected; the ages of the patients were from 9 to 16 years. The type of disease was only moderately severe, and the number of cases with complications was five. There was one of pneumonia with double otitis, two of broncho-pneumonia, and one of otitis. Both cases of otitis had immediate paracentesis. One (no amidopyrin) healed in two days without otorrhoea, the other boy (amidopyrin) had a double otitis, which developed into a profuse otorrhoea and took two weeks to heal, clearing up without any impairment of function. This boy also had a severe treble lobar pneumonia. Eventually he made a good recovery and has remained well since.

Without going into details, the only improvement noted either by the nursing staff or myself was that the boys having amidopyrin were more comfortable, seemed less ill, and wanted books. The only further treatment (routine for all boys) other than occasional was purgen in appropriate doses as required, and the usual mixture containing vin. ipecac., sp. aeth. nit., liq. ammon. acet. co., and tinct. camph. co. in amounts proportionate to age, during the febrile stage.

The amidopyrin was given in aqueous solution in doses of 1½ to 3 grains four-hourly until the temperature remained normal for twenty-four hours, dosage being varied proportionately to age. The cases were not selected. The use of amidopyrin was begun with the third batch of cases—namely, the ninth case—and was thereafter given to every alternate case. Careful notes and charts were kept of all cases. It may be objected that the dosage was too small to allow of a definite conclusion being drawn, but if the drug has a definitely specific action one might, I think, fairly expect some indication, having regard to the number and age of those treated, and the possibility of controls. I append a summary of results.

	Cases Treated	Days of Temperature	Total Days Ill	Complications
Amidopyrin ...	56	4.75	23.7	Mild broncho-pneumonia (2 cases). Treble lobar pneumonia with double otitis followed by otorrhoea (1 case).
No amidopyrin	66	5.0	22.4	Mild broncho pneumonia (1 case). Single otitis (1 case).

—I am, etc., G. E. FRIEND,
Medical Officer, Christ's Hospital; President, Medical Officers' Association.

Horsham, Dec. 18th, 1930.

NATURAL LABOUR FOLLOWING CAESAREAN SECTION

SIR,—In view of the reports from leading obstetrical clinics of natural labour following Caesarean section which have already been published I should have hesitated to make any reference to the following case, but on second thoughts it occurred to me that there are points about it which might be of interest to your readers.

In the middle of the night of May 2nd, 1925, a married woman, aged about 30, whose abdomen was fat and pendulous, and who had previously given birth to six children, was admitted to the Lloyd Hospital, Bridlington, from the depths of the hinterland, in a state of tonic contraction; the uterus was tightly moulded about the foetus, which was lying in the transverse position with one arm presenting. She had been in labour for twenty-four hours, and was crying out from the continuous pain; her pulse rate was 120 per minute. I did not dare to attempt version and delivery *per vias naturales*, and decided that the only alternative was to risk Caesarean section, embryotomy promising to be just as dangerous as version. I operated at once, and delivered a living child. The mother was pyrexial during the first two weeks of convalescence, but the abdominal wound healed soundly. The baby was a fine specimen, but later the news reached me

that the mother had mistaken him for a pillow one night with disastrous results.

I next heard of this woman in September, 1927, when she reported to me that she was again pregnant. Obsessed with the fear that the uterine scar would give way, I took her into hospital, and in March, 1928, I successfully delivered her. Forceps were applied simply because, after reading in the *Transactions* of the Royal Society of Medicine about the woeful effects of weak Caesarean scars, I trembled to submit my work to any extra strain. I suggested to her this time that she had done her duty to the State, and might now rest on her laurels, but, nothing daunted, she appeared again in November, 1929, was again admitted to hospital, and this time delivered herself unaided, after an hour's concentrated effort, of a boy weighing 10 lb.

At the time of writing, a message has reached me that the patient is once more pregnant.

It may be that this case might be cited as a strong argument in favour of sterilization being effected whenever a Caesarean section is performed; it might equally well be used in favour of the opposite point of view. —I am, etc.,

Bridlington, Dec. 22nd, 1930. C. J. GORDON TAYLOR.

TREATMENT OF VARICOSE ULCERS

SIR,—I have read with interest the method of treating varicose ulcers employed by Mr. Dickson Wright, in the *Journal* of December 13th, 1930. I have also seen the cases so treated and demonstrated by Mr. Wright at the Royal Society of Medicine (Dermatological Section) meeting last February, and note that he advocates intravenous injections by sclerosing solutions where possible, plus application of supporting bandages to the leg. To me it seems difficult to assess in what proportions credit must be assigned to these two methods when used simultaneously, both of which aim at preventing venous stagnation. There is no doubt whatever that one can get very good results from either method alone or conjointly, but it would appear to me that by means of supporting bandages alone this would only have a temporary effect, because as soon as the bandages are finally removed one would get the reflux pressure in the veins, putting the hydraulics all wrong once more in the affected parts, and then it is only a matter of time till the former trouble returns. With intravenous sclerosing treatment one breaks the downward and backward hydraulic pressure of the column of blood in the affected vein more permanently, and from a purely mechanical point more effectively.

I think that undoubtedly we get our best results by this latter method in cases where there is only one single long varicose vein, or where the vein can be treated before it has ramified very much—for example, when the internal saphenous vein can be injected in the middle third of the thigh or soon after it leaves the saphenous opening. If the veins have branched very much, then I think one gets results in direct proportion to the number of ramifications that one can effectively deal with and sclerose permanently.—I am, etc.,

Leicester, Dec. 26th, 1930. F. A. E. SILCOCK, M.D.

THE STETHOSCOPE AS AN AID TO PERCUSSION

SIR,—I was very much interested in Dr. Hawthorne's letter in the *British Medical Journal* of December 20th, 1930, on the above subject. I have been practising percussion exactly as described by him for the last three or four years, and can testify to the assistance afforded by the method in detecting slight alterations in the percussion note. I rather imagine that a good many people must have discovered this trick for themselves, although Dr. Hawthorne's communication is the first in which I have seen it described. A much travelled colleague of mine, to whom I mentioned what I imagined to be my "discovery," told me that he had seen it practised by French paediatricians. Incidentally, the method is particularly valuable with the light percussion required in examining the chests of small infants. Indeed, so difficult is it sometimes to detect small differences in the note in the very young that some American paediatricians claim to rely more on the sense of resistance conveyed to their fingers than on differences of note conveyed to their ears. I think that if they would practise Dr. Hawthorne's method they would find themselves again placing reliance on their auditory sense.—I am, etc.,

Aberdeen, Dec. 24th, 1930. E. R. C. WALKER.

SIR,—Whatever appears from the pen of Dr. Hawthorne is always interesting, often suggestive, and sometimes instructive; but when he goes the length of asserting that deafness is an aid to percussion this is more than our credulity is at first sight willing to accept. He does not actually make this assertion, but that is what it amounts to when he says that "the percussion note appears to him to gain in distinctness" when he has limited his hearing power by wearing a binaural stethoscope with "the bell allowed to dangle." He must explain the increase in distinctness, if it is real, in some way other than aural. There is, however, a method of combining the use of the binaural stethoscope with percussion which is obviously of so great value that one is surprised it is not more commonly taught. As many of your readers must be well aware, the ease and certainty in defining a solid organ is greatly aided by the binaural stethoscope if the bell is placed over the organ and its margin percussed. The change from the low-pitched clear to the dull high-pitched note of the solid organ is accentuated. The liver and the heart of a fat subject can be defined by this method with a degree of accuracy not possible by ordinary percussion.—I am, etc.,

London, Dec. 26th, 1930. ARISTOTLE.

ACUTE ARSENICAL POISONING

SIR,—The report of Dr. A. Wotherspoon under the heading of "Arsenic in sweets," in the *Journal* of September 20th, 1930 (p. 492), prompts me to record another case of accidental poisoning with arsenic, in which ten people took large doses, with only three deaths.

A family of seven half-castes, two Samoans, and a Solomon Islander partook of pancakes for breakfast at 7.30 a.m. The Solomon Islander, who cooked for them, having run out of baking powder that morning, went across to the Chinese quarters close by, and there found a tin labelled "baking powder," and practically full (about 3 oz.) of a white powder. He took this, and emptied it all into a frying-pan with flour, etc., to make the pancakes. All the family ate the pancakes, some more some less, one Samoan saying that he himself ate two and a half; all vomited shortly after eating, but only two thought that the pancakes had an unusual flavour. They were brought to the hospital at 10 a.m. On arrival none seemed at all ill; in fact, the adults walked to their quarters. None complained of diarrhoea or of abdominal pain on admission.

It took a good while to elicit from the Solomon Islander what had occurred in the making of the pancakes, and as it was thought that potassium oxalate might be the cause of the poisoning it was decided not to wash their stomachs out, more especially as most of them had vomited again on admission. At 11 a.m. they were all given magnesium sulphate, which in most instances made them vomit again. One child had a bowel action shortly after this. Nothing abnormal was noted, excepting nausea, until 12 noon, when four of the younger ones showed signs of heart failure, stimulants and saline enemata being given. At 2 p.m. a girl, aged 6, collapsed, and died ten minutes later, the face becoming livid, the lips cyanosed, and the heart and respiration failing together. A boy, aged 4, became very drowsy

at the same time, though pulse and respiration remained normal; his drowsiness increased, and at 8 p.m. he had violent convulsions, followed by death at 9 p.m. In the meantime the baby, aged 2 (the child whose bowels had acted after the magnesium sulphate), also became drowsy, and at 5 p.m. had a series of convulsions, which terminated in death at 5.15 p.m.; one girl of 5 years was ill for a week, and then recovered. The father (30), mother (24), and a boy (3) had very few symptoms, chiefly nausea and headache, and all three were convalescent in three days. The Solomon Islander (30) and two Samoans (20 and 10 years) only suffered from vomiting and drowsiness, and soon recovered.

Several portions of pancakes were tested by the Government analyst in Auckland, whose report stated that "the pancakes contain arsenic equivalent to approximately 55 grains of arsenious oxide in one pancake; the traces of white powder in the tin are highly arsenical, and appear to consist principally of arsenious oxide."

Dr. E. Hunt, who was in charge of the cases, has supplied the clinical notes, and Mr. K. M. Griffin, M.Sc., A.I.C., the analytical report.

The arsenious oxide appears to have been in regular use for the curing of skins in this district, but how it came to masquerade as "baking powder" is a mystery. These cases are of interest because of the huge doses of arsenic taken, for even the baby was said to have had half a pancake, and the others much larger amounts. The recovery of so many of the patients must have been due to the rapidity and relatively complete ejection by vomiting of the arsenic still retained in the pancakes.—I am, etc.,

J. SCAIFE ARMSTRONG, M.B., Ch.B.
Late Medical Officer in Charge, Apia Hospital, Samoa.

Taupo, New Zealand, Nov. 15th, 1930.

SIR,—As the symptoms and progress in a case of acute arsenical poisoning are variable, such cases are worthy of record. The following occurred in a girl, aged 18, who took one teaspoonful of arsenious acid mixed with treacle, and soon afterwards retired to rest at about 9 p.m. An hour later she was seized with vomiting and diarrhoea, which lasted through the night.

She was first seen by me at 7 a.m. on October 22nd, 1930, and was then in a state of collapse, the pulse being feeble and the skin cold. She was slightly cyanosed. She complained of pain in the stomach, thirst, dryness of the throat, and profuse vomiting and diarrhoea, which occurred simultaneously every fifteen minutes or so. She drank large quantities of fluid and immediately vomited them. She was mentally normal, and answered all questions intelligently. The vomiting and diarrhoea continued throughout the day, but she became considerably more cyanosed, and complained of violent attacks of intestinal colic. She died about 5 p.m. the same day. At the post-mortem examination the stomach was large and distended, showing great venous engorgement externally. On opening there was much gas and 1½ pints of bile-stained fluid containing yellow necrotic debris. The mucous membrane lining the stomach was very inflamed, being most marked in red streaks corresponding to the rugae. This was especially noticeable in the most dependent part of the stomach, towards the pylorus. There were several large yellow necrotic areas in this region. The stomach was lined with a tenacious mucus. The duodenum and small intestine were inflamed and distended in their whole length, having a dusky cyanosed colour externally. The intestine contained a bile-stained fluid similar to that in the stomach, and its mucous membrane was inflamed in its whole length. The large intestine was completely empty and firmly contracted in its entire length. The kidneys and peritoneum were injected.

The interesting point about the case seems to be the absence of nervous symptoms and the clearness of the mental condition up to the end.—I am, etc.,

F. V. ALLEN.

Saainton, Yorks.

THE GENERAL PRACTITIONER AND POISONING CASES

SIR,—Having had a good deal to do with poisoning cases in India I sympathize with the general practitioner who seldom sees one. On reading the poisoning cases which come before the coroner we often see how many of them were signed up in the first instance as death from natural causes, and that it is only when the criminal goes once too often that suspicion arises, and then follows the exhumation of other victims of the same criminal. Arsenic is the agent used in nearly all cases. The symptoms in the slow poisoning case may be merely intense depression, and the more acute cases may show nothing more. The real acute cases imply vomiting and diarrhoea. Peach-blossom-coloured patches over the bony prominence of the knuckles, elbow, malleoli, etc., are not infrequent, and in themselves should at once arouse suspicion. The classical symptoms are, of course, described in any book on toxicology.

I would suggest that every general practitioner coming across cases not clearly intelligible should take a sample of the urine and himself do a provisional Marsh test, and if arsenic is present seal up the rest of the sample. I have frequently had detected arsenic and datura in urine from patients, some of whom died and some lived. If this precaution be taken it will prove satisfactory both to the practitioner and to the Crown.—I am, etc.,

HENRY SMITH, C.I.E.
Lieut.-Colonel I.M.S. (ret.).

Sidcup, Dec. 18th, 1930.

AVERTIN ANAESTHESIA

SIR,—In reply to Mr. Basil Hughes's question in your issue of December 20th, 1930, the patient who developed broncho-pneumonia following partial gastrectomy under avertin and local anaesthesia was given no morphine or morphine derivative before, during, or after operation.—I am, etc.,

C. LANGTON HEWER.

London, N.W.1, Dec. 27th, 1930.

SIR,—Mr. Basil Hughes is a very enthusiastic user of avertin and gets wonderful results; I have seen some of them. At the same time I feel that on the question of anoxaemia he turns a somewhat blind eye to what is undoubtedly a drawback to the use of avertin. The patients whom I saw were all breathing with a considerably diminished respiratory excursion, and were mostly somewhat cyanosed. The recovery period being so long (said to be delayed in some cases for over twenty-four hours) diminished respiratory exchange must result in suboxygenation, and this cannot be a good thing. This may be more than counterbalanced by good points, but it is no use ignoring it. As gas and oxygen is recommended to supplement the basal anaesthesia of avertin, and is no doubt ideal, as Mr. Hughes says, I think the same result can be obtained with less risk and trouble by using omnopon and scopolamine in suitable doses, and then following with gas and oxygen. In children luminal by the mouth answers admirably.

There are quite a lot of contraindications given in the makers' literature for avertin. I know of none for gas and oxygen with suitable premedication. In my opinion there is nothing so good as a light gas and oxygen combined with local anaesthesia with novocain in a strength of 1/2 per cent. to 1 per cent. It gives all the relaxation that can possibly be required, and a swift recovery with a minimum of after-effects.—I am, etc.,

E. J. CHAMBERS.

Doncaster, Dec. 20th, 1930.

PROPHYLAXIS IN MIDWIFERY

SIR,—In answer to the letter by Dr. Moir in the *British Medical Journal* of December 20th, 1930 (p. 1066), I would suggest the use of glauramine and glycerin in midwifery. I have used this preparation for some years, not so much in normal labour, but more particularly in those cases where frequent vaginal examinations have been made, and in prolonged or difficult labour. I have been very pleased with the results.

The vagina is filled before and after delivery with glauramine in glycerin, 1 in 60; following any intra-uterine manipulation, such as manual removal of the placenta, the uterus is swabbed out with 1 in 20, and then a wick of gauze, soaked in 1 in 60, is inserted into the uterus and the vagina filled with 1 in 60. In cases of Caesarean section following a long labour or vaginal examinations, prior to operation the vagina is swabbed out with glauramine in spirit, 1 in 10, the abdomen is prepared with the same strength, and if possible a swab soaked in this is pushed through to the vagina. No irritation has occurred after the use of this preparation, such as may occur after picric acid or iodine. A full report on the bactericidal properties of auramine (the active principle of glauramine) was published in the *Journal of the Royal Society of Arts*, March 16th, 1923.

For several years calcium salts have been given daily to all pregnant women at Crumpsall Infirmary, and in many cases artificial sunlight has also been used. It has been noticed that the calcium not only checks the tooth-ache which so often occurs in pregnancy, but also seems to save the teeth from further rapid decay.—I am, etc.,

Manchester, Dec 29th, 1930. F. H. LACEY, M.D.

MENTAL TREATMENT ACT, 1930

SIR,—The draft Rules and Orders coming into effect on January 1st have been published. Possibly these are open to subsequent amendment in the light of experience and criticism The hope is that mental illness treatment should be conducted as nearly as possible on the lines of physical illness treatment; that the private specialist and general practitioner should be encouraged to take an active part in the service; and that all suggestions of mental hospital treatment and its administration should be kept as far out of the picture as possible.

The use of the private doctor's house for voluntary and temporary patients is a part of the scheme much to be advocated, and therefore the Rules and Orders should not prove either irksome or a deterrent. These rules contain no definition of a "nursing home," and, in consequence, we must accept it that the definition given in Section 10 of the Nursing Homes Registration Act, 1927, holds the field. Under this definition the private practitioner who receives a patient, *and provides an attendant*, will find that his house has become a "nursing home." For such there are certain Rules and Orders of the Board of Control that differ from those for "a single patient." Which has he to be guided by? Then, certain of the rules do appear to be in part objectionable. Possibly they can be modified. For instance, Nos. 38, 103, 107, and 121 appear to be inquisitorial; Nos. 55 and 59, 101 and 116 appear contradictory; No. 34 destroys, by requirement of notices to be displayed, the atmosphere of a private house; Nos. 93 to 95, 102, 106, 108, and 122 would prove onerous. In the past there has been no obligation on the doctor or person relinquishing charge of "a single patient" to provide his successor with any particulars of progress more recent than those included in the original certification documents. In consequence, the patient has not been placed in the best position for continuance of treatment; this hiatus has not been safeguarded in the rules as it should be, especially in the case of voluntary and temporary patients.—I am, etc.,

Hove, Dec. 10th, 1930. E. ROWLAND FOTHERGILL.

MIGRATION AND HEALTH

SIR,—Permit me to substitute "sixth" for "fourth" in the statement "there is no one living in Australia (other than the Aborigines) who is a descendant of the fourth generation of Australians" in my paper published in your issue of September 27th, 1930.

My friend Dr. Antill Pockley, president of the Australasian Medical Congress held in Sydney in 1911, is of the third generation, his grandmother being Australian born, while his grandchildren are of the fifth generation. Mrs. E. I. Ross of Pymble, Sydney, writes: "In my family there are more than 200 fourth-generation Australians, and more than 100 of the fifth generation. The original pair were born in Windsor, New South Wales." Mrs. Ada Brennan of Darlington writes: "I beg to state that there are sixth-generation Australians to my knowledge—my grandmother, born in Liverpool, N.S.W.; my mother, born in Liverpool, N.S.W.; my sister, born in Picton, N.S.W.; her daughter, born in Sydney; her granddaughter, born in Sydney; her great-grandson, born in Sydney. On my father's side there are five generations, all Australian born."

As it is only 142 years since the arrival of the First Fleet and the founding of the Settlement by Governor Phillip, it will be safe to say: "There is no one living in Australia (other than the Aborigines) who is a descendant of the sixth generation of Australians." With regard to the fourth generation, as they say in the Army, "The error is regretted."—I am, etc.,

J. S. PURDY, M.D.
Metropolitan Medical Officer of Health.

Sydney, Nov. 5th, 1930.

MEDICAL RECIPROCITY WITH FRANCE

SIR,—Mr. E. Gerald Stanley, writing from Paris, disagrees with my conclusion that the time is ripe for the question of equitable medical reciprocity with France to be taken up. His objections are based on (1) the medical congestion already in France, (2) the doubtful success of any attempt to reopen the question, and (3) that "an Englishman would be ill advised to avail himself of it if ever it were granted." Overcrowding in France does not, however, affect the question. The crowds of Poles and Italians in France, to which Mr. Stanley refers, are workmen, not medical men. Were they the latter, it would argue that Englishmen should be included, not excluded. Moreover, Englishmen do not practise in France directly in competition with others. Their interest is with their own countrymen, whom they largely attract; and who, but for them, might not be there. They very rarely see a French patient. Naturally the French are pleased to secure English patients and their fees, but our claim to both is greater than theirs, and deserves consideration.

That an application for reciprocity would be turned down, as Mr. Stanley asserts, is unlikely, if properly presented. France has now a free hand, and is friendly. The inequality of the present arrangement is palpable, and a demand for reciprocity, limited to, say, a maximum of 100 medical men, would not be alarming, while it would meet the situation. Mr. Stanley's third objection, that a practice in France is better avoided by an Englishman, is a strange one. Many English medical men desire to practise in France largely for the sake of their health, and do not wholly depend on professional success for an income. Four English doctors are allowed in the Princi-

pality of Monaco, and four are always found there, in spite of Mr. Stanley's jeremiads. A similar number could practise with equal advantage in Mentone, Nice, and Cannes, and though Mr. Stanley says "English practitioners are not wanting in Paris," they soon will be as scarce as on the Riviera, unless a more generous reciprocity is arranged.

The statement that there is no prospect of hospital practice for the foreigner is not convincing. The Queen Victoria Memorial Hospital at Mont Boron, near Nice, was staffed by Englishmen while they could be secured, and I have known Englishmen on the staff of the British Hospital in Paris. It is not for hospital practice, however, that reciprocity is asked, but for admission into France on conditions more or less on a par with those allowed to French medical men here, limiting the number so allowed, to prevent arousing general professional jealousy. Reciprocity could surely be arranged with France as it has been with Italy. Cannes and Mentone were practically launched by Englishmen, and the Riviera has developed largely through their support, and that of the British medical men who have practised there. The latter can now only be replaced if medical reciprocity be put on a fairer and more reasonable basis.—I am, etc.,

Topsham, Devon, Dec. 15th, 1930. D. W. SAMWAYS.

Obituary

CHARLES ALGERNON STIDSTON, D.S.O. M.D., B.S.

Honorary Surgeon, Royal Hospital, Wolverhampton

Mr. C. A. Stidston, who died on December 15th, after an illness of five months, in his fiftieth year, was the son of the late Charles Stidston of Plymouth. He was a student of St. Bartholomew's Hospital, where he gained the Foster Prize and the Wix Prize, and after graduating M.B., B.S.Lond. in 1906 was appointed a house-physician. He went to Wolverhampton in 1907 as resident medical officer of the General, now the Royal, Hospital. He was elected honorary assistant surgeon two years later, and full surgeon in 1920. On the outbreak of war in 1914 Mr. Stidston, who was a Territorial officer in the R.A.M.C., was called up with his field ambulance, the 2/3rd North Midland. He served for the whole duration of the war, and was for eighteen months at the front in France. He was in command of his field ambulance during the difficult and anxious fighting which followed the battle of Cambrai. For his services in the field on this and other occasions he was awarded the D.S.O. At the end of the war he retired with the rank of lieutenant-colonel, and resumed his practice at Wolverhampton. His inventive turn of mind was shown in a portable operating table described by him in the *Lancet*, and in the portable sterilizer, the outfit for immediate treatment of cases of poisoning, and the anaesthetist's screen, of which descriptions were published in the *British Medical Journal*. He leaves a widow and one daughter. The following appreciation of his character and career is sent by one of his hospital colleagues.

Charles Algernon Stidston, whose loss is deplored not only by his colleagues and friends, but by the inhabitants of Wolverhampton and South Staffordshire, among whom he lived and practised for twenty-one years, was a man of original and striking personality and of brilliant and varied gifts. His abounding vitality, his charm of manner and breadth of human sympathy, earned him the devotion of his patients, rich and poor alike. He had a lively and spontaneous wit and a gift of expression, both in speech and in writing, which were the delight of his friends. He could be pungent on occasion, but even his victims were ready to forgive him for his wit, and enjoy a laugh against themselves. He was the warmest, the most faithful, the most generous of friends. He had his fierce hatreds too, for there was nothing half-hearted about him. To serve a friend no effort and no sacrifice were too great. With equal prodigality he spent himself in serving many who had no claim but their needs and his own generosity.

For twenty-one years he was a member of the honorary surgical staff of the General, now the Royal, Hospital, Wolverhampton, and he threw himself into his work with the zest and devotion which he displayed in all his pursuits. Although he had a large and very successful general practice, it was his ambition and intention to devote himself entirely to surgery as soon as circumstances permitted. It was a tragic disappointment to find himself disabled by the illness to which he finally succumbed, at the very moment when he saw the prospect of realizing his ambition. For five months he lay ill and almost helpless. He never murmured or complained, and bore himself throughout with characteristic dignity and fortitude. Even his wit and humour did not forsake him, for he jested lightly with his nurse a few minutes before his end; which came suddenly.

His record as a soldier is fine and characteristic. He served with distinction for eighteen months in the front line, careful of those under his command, careless of his own welfare. Though only once slightly wounded he suffered from gas, and there is no doubt that this and the normal hardships of active service at the front undermined his naturally robust constitution and contributed to the illness from which he died. Though he had a right to be proud of his military record, like many other gallant soldiers he rarely spoke of it. Courage, generosity, and modesty were parts of his nature, and they displayed themselves equally in war and in peace. He will live long in the memories of all who loved him. And those who knew him best loved him most.

FREDERICK W. BENNETT, M.D.

Consulting Aural Surgeon, Leicester Royal Infirmary

Leicester has lost a many-sided citizen by the death of Dr. F. W. Bennett. After studying at Owens College, he became M.R.C.S. in 1883, and a year later graduated M.B.Lond. with honours in medicine; in 1885 he proceeded to the degree of M.D. After holding resident posts at several Manchester hospitals he started practice in Leicester, and was soon appointed to the staff of the Infirmary as honorary assistant physician. But he was attracted to what was then a new specialty, that of laryngology. Several of the larger hospitals were creating departments for diseases of the ear, nose, and throat, and as there was very little teaching in this country Bennett went to Vienna. On his return he was appointed the first aural surgeon to the Leicester Infirmary; he remained faithful to his choice, and continued to hold this post for nearly thirty years. The way of a pioneer is always difficult, and Dr. Bennett found that he was hampered at the beginning of his work by lack of accommodation and of assistants. His beds were scattered in various medical and surgical wards of the hospital, and he was only allowed to do minor operations, such as the removal of tonsils and adenoids. It was typical of the man that, in order to improve working conditions, he engaged a nurse from outside the hospital at his own expense. By his energy, his skill, his personal charm, and his friendly relations with colleagues, he succeeded in overcoming all his difficulties, and when he retired from the active staff he left a department well equipped, greatly enlarged, and fully recognized as an important branch of the hospital. He was at one time a prominent member of the Section

of Laryngology of the Royal Society of Medicine, but retired immediately after the war as a protest against the exclusion of foreign members.

Dr. Bennett will be remembered with the kindliest feelings by his professional brethren in Leicester, and by the general public, because he was a man of many and varied interests, fond of music and enthusiastic in several branches of science, including geology. He took the degree of B.Sc. twenty years after he qualified in medicine. Until his death he was president of the Section of Geology in the Leicester Literary and Philosophical Society. He spent many holidays in Switzerland studying glacial action, and he was regarded as the authority on that perpetual puzzle to geologists, the rocks of Charnwood Forest. For several years he was a member of the old School Board, and in 1891 he drew up a scheme for the training of teachers in elementary science. He was a co-opted member of the City Museum and Library Committee, an early supporter of the local University College, and a member of its council. Such public work was real pleasure to him, and he carried on his duties manfully, although latterly he had suffered from a failing circulation. His end came suddenly, as he had often expressed a wish that it might. On the last evening of his life he was at a committee meeting; although he went to bed well, he had an anginal attack during the early hours of December 3rd, and passed away in it. He leaves two daughters.

A. L. McL.
A. V. C.

The death took place at Bridge of Allan, on December 14th, 1930, of Dr. J. HOSACK FRASER, F.R.C.P.Ed. Dr. Fraser had been in poor health for several months, but had been engaged in professional work up till a few days before he died. Dr. Fraser was born in 1857, and after graduating M.B. at Edinburgh in 1881, he became resident physician with the late Sir Thomas Fraser. He afterwards engaged in hospital work at Lancaster Royal Infirmary, and went for a trip round the world as a surgeon. On returning to Scotland he settled down some forty years ago in Bridge of Allan, where he was for many years one of the best-known physicians. He joined the Royal College of Physicians of Edinburgh as a member in 1895, and proceeded to the Fellowship in 1897. He was the author of various communications to medical journals, including one on syphilitic tumour of the cerebellum, contributed to the *Lancet* in 1883, and one on hysteria and metallotherapy, contributed to the *Birmingham Medical Review* in 1884. During the war he acted as medical officer at the Keir House Auxiliary Hospital, and was presented with the Belgian King Albert medal in recognition of his services. He is survived by a family of sons and daughters.

Dr. WILLIAM DYNE STEEL died on November 21st, 1930, at Abergavenny, where he was born seventy-five years ago, and of which borough he was an honorary freeman. He received his medical education at Aberdeen, King's College Hospital, and the London Hospital. He graduated M.B., C.M Aberd. in 1881, and proceeded M.D. two years later. After graduating, he joined his father in the practice in Abergavenny which had been founded by his grandfather. He held the appointment of senior physician to the Victoria Cottage Hospital, the establishment of which was largely due to the activities of his father and himself. He was medical officer of health for the borough from 1883 until 1926. Dr. Steel joined the Volunteers in 1879, and was awarded the Volunteer Decoration in 1900; five years later he became colonel in command of the 4th Volunteer Battalion of the South Wales Borderers. When the Territorial Force came into being he raised and commanded the 3rd Battalion of the Monmouthshire Regiment. He retired in March, 1914, after two extensions, but rejoined early in the war, raising and commanding the 3rd Battalion of his old regiment until illness compelled him to retire in 1916. He was appointed deputy lieutenant for the county of Monmouth in 1914. He was an Honorary Associate of the Order of St. John of Jerusalem, and for many years lectured and examined for that Order. He was the first chairman of the Monmouthshire Panel Committee, and retained that office until his retirement from practice in 1928.

Dr. ARTHUR FOSTER, who died at Worcester on December 13th, 1930, was born in 1872, and received his medical education at Edinburgh University where he graduated M.B., Ch.B. in 1893, proceeding M.D. in 1897. He commenced to practise in Blackburn, his native town, but after a few years moved to Inkberrow, Worcestershire, and thence to Leicester, where he built up a large practice, and was appointed assistant physician to the Leicester Royal Infirmary. He studied law, became a member of Gray's Inn, and was called to the Bar in 1912. In 1920 he found the strain of practice too great and went to Worcester. While in Leicester he had held the post of honorary secretary to the Panel Committee from 1916 to 1920, represented the Committee at the annual conference, and had been a member of the Insurance Committee and of the Medical Benefit and Allocation Subcommitees. He was a member of the board of management of the Leicester Public Medical Service from its inception in 1913 until 1920, during which latter year he was vice-chairman. In the war he held the commission of Captain R.A.M.C.(T.), and was attached to the 5th Northern General Hospital. Of his life in Worcester a colleague writes: Dr. Arthur Foster was a man who always gave of his best, not only to his patients, but also to his professional colleagues, by every one of whom he was trusted and respected as a straight man and a sound counsellor. He was for many years the honorary secretary of the Local Panel and Medical Committees for the City of Worcester, and was medical representative on both the City and the County Insurance Committees. He always had the work at his finger-tips, and was unsparing of himself in carrying out the duties. He was also for many years the local representative at the Panel Conferences. He was an active member of the British Medical Association, and for a short time acted as representative. In spite of a busy practice he found time to devote to civic life, and in 1924 was elected city councillor, a position he held at the time of his death. He was an active member of the Elementary Education Subcommittee, and was for a short time its chairman. He was also a very active and regular member of the Health Committee, on which his professional knowledge was invaluable. His son, Dr. Kenneth Foster, has been associated with him for about three and a half years in the practice. The Medical Secretary adds: "Dr. Foster will be greatly missed centrally as well as locally. He was a man who could always be relied upon for work for his profession, whatever the other claims upon him, and his judgement and cheerful co-operation were always at the disposal of the Association."

Dr. HECTOR MCLEAN WILSON, who died at Leeds on December 22nd, 1930, was a well-known authority on public health, especially with reference to river conservancy and the purification of sewage. He graduated M.B., C.M. at Edinburgh in 1882, and proceeded M.D. in 1890. Sir Alexander Houston writes: On the eve of Christmas, just when one's thoughts were turned to gladness, the sad news reached me of the death of Dr. Hector McLean Wilson, a friend of forty years' standing. He was several years my senior, and was building up a good practice at Penrith when the lure of preventive medicine proved too strong for him. He went back to Edinburgh and we studied science together, taking our B.Sc. at the same time. Thus began a lifelong friendship, now unhappily terminated by death. Wilson had great intellectual gifts and the highest sense of honour, combined with a personal charm which was almost irresistible. These gifts, aided by a keen sense of humour and great tactfulness, carried him most successfully along the long road he had set out to travel. For twenty-five years he served as chief inspector of the West Riding

Rivers Board. That Board is now known all over the world, and there is no doubt that Wilson's work did most to place it on its present pinnacle of greatness. His patience, sagacity, imagination, and foresight were acknowledged by all those who came into contact with him; he had no enemies, but a host of friends, amongst which the writer counted himself one of the oldest and most admiring. He has passed away, but his life was not lived in vain; he not only did splendid work himself, but he was a positive inspiration to all those who laboured in the same vineyard. None of us in the service of preventive medicine and the conservancy of our rivers can hope to leave behind us a finer, cleaner, friendlier, or more enduring record than did my dear friend Wilson.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Trade Disputes and Trade Unions (Amendment) Bill and the Representation of the People Bill have been presented in the House of Commons. One of the provisions of the latter Bill proposes to abolish university constituencies.

The House of Commons will reassemble on January 20th and the House of Lords on January 28th.

The Census Order

In the House of Commons on December 15th, 1930, Sir DENNIS HERBERT asked what the Government intended by Section 13 of Part II of the Second Schedule to the draft of the Census Order, 1930. Mr. CRAIGIE AITCHISON (Lord Advocate) said that this item inquired whether the person enumerated was "entitled to medical benefit under the National Health Insurance Acts." Under the Census Act, 1920, such an inquiry needed to be sanctioned by a resolution of the House of Commons. The information was desired to provide a check on the index registers of Insurance Committees. A precisely similar question had been issued in Scotland for the 1921 census. In Scotland to-day inquiries were being carried out to ascertain the incidence of disease among insured persons, and the answers to Question 13 in the draft Census Order would facilitate that inquiry.

The House then passed the necessary resolution authorizing the question.

A National Maternity Service

In reply to Dr. Fremantle on December 18th, Mr. GREENWOOD said that he would consider the suggestion that, before any scheme for a national maternity service is formulated, he would confer with the midwives through the Incorporated Midwives Institute and the Queen's Institute of District Nursing, as the respective bodies mainly representing and employing them, as well as with bodies representing the medical, professional, and other interests concerned. Asked by Dr. Fremantle whether it was not essential that the midwives' profession should be considered and included in the circular, Mr. GREENWOOD pointed out that the circular was addressed to local authorities, and not to other bodies. Dr. FREMANTLE asked whether the circular said that Mr. Greenwood had consulted other professions, when he had not consulted the profession of midwives. Mr. Greenwood did not reply.

Replying to Viscountess Astor on December 18th, Mr GREENWOOD said that, as stated in a circular recently issued to local authorities on the subject of maternal mortality, the Government had decided to undertake negotiations with authorities concerned to formulate a scheme on a national basis for the care of maternity. Such negotiations were a necessary preliminary to the introduction of legislation for the purpose.

Pensions

Replying to Dr. Morris-Jones on December 15th, Mr. ROBERTS said assessment of pensions was based on the degree of physical loss or incapacity sustained by an officer or man in consequence of a particular injury or disease, not merely on the clinical signs present in the case. Dr. Morris-Jones asserted that in certain cases of pulmonary tuberculosis, although there might be extensive physical signs in the chest, a decision had been given that this did not necessarily indicate a high degree of disablement, and that the presence of tubercle bacilli in the sputum did not mean that the man was totally disabled. Mr. ROBERTS said this assertion far from adequately represented the principles on which medical officers of the Ministry worked. It was never the case that an assessment was reduced simply because a man was at work, though the extent, if any, to which the man had shown himself capable of regular work was necessarily some evidence of capacity.

Mr. F. O. ROBERTS, on December 15th, told Mr. Price that the total number of officers and men at present in receipt of pension on account of neurasthenia was about 32,600. It was the policy of the Ministry to make final awards in all suitable cases, and in 78,000 of the total number of cases referred to the awards had been made permanent.

Mr. F. O. ROBERTS stated that the number of in-patients (apart from those in mental institutions) at the end of November, 1930, was about 4,100, and the number in mental institutions on the same date about 6,400.

Encephalitis Lethargica

On December 19th Mr. FREEMAN asked Mr. Greenwood whether, in view of the figures given in the annual report of the Chief Medical Officer for 1929, which showed that, while 1,036 cases of encephalitis lethargica were notified during the year 1929, the actual number of deaths for that year as recorded by the Registrar-General was 1,037, he could say what proportion of the deaths in question had been previously notified as cases of the disease.

Mr. GREENWOOD replied that he could not say. Deaths from this disease in any year included a number of cases notified in previous years.

Mr. FREEMAN asked what steps would be taken to compel doctors to notify the disease. Mr. GREENWOOD said that encephalitis lethargica was compulsorily notifiable in England and Wales under Regulations made in 1919. He had no reason to think that medical practitioners failed to comply with their obligations under the Regulations.

Sickness Rates among Seamen

Mr. W. GRAHAM, on December 16th, told Mr. T. Lewis that an investigation was being made to determine the true death and sickness rates among seamen, compared with other occupations. The accommodation on board ship, which was frequently inspected by the surveyors of the Board of Trade and by the local health authorities, had recently been engaging the special attention of the Board of Trade, of the Joint Committee of the Board of Trade and Ministry of Health, and of the Shipping Federation. He hoped that agreed proposals improving the general standard of crew accommodation would result from these inquiries.

Thyroid Extract.—Mr. TINNE asked Mr. Clynes on December 19th whether, in view of the increasing use of preparations of thyroid extract and of its effects, he would take steps to bring this drug under the Dangerous Drugs Act. Mr. CLYNES said he was advised that thyroid extract was not a drug which would be productive of ill effects similar or analogous to those produced by morphine or cocaine, and that consequently it was not a drug to which the Dangerous Drugs Act could be applied.

Poison Gas Experiments.—Mr. SHAW told Mr. Freeman on December 18th that since January 1st, 1929, some 520 volunteers had undergone tests in poison gas experiments with the object of proving the efficacy of preventive and curative treatment for skin burns and of confirming the adequacy of the protection afforded by respirators. Many of these volunteers had undergone more than one test. Every care was taken to ensure that the test involved no risk to the health of the volunteers. If an injury were sustained, it would be dealt with as attributable to service, and compensation would be paid from Army funds.

Tin Poisoning from Cheese Wrappers.—Mr. GREENWOOD stated, in reply to Major George Davies on December 18th, that he had received a communication from the Lambeth Borough Council enclosing a report in which the medical

officer of health made a statement concerning the possibilities of tin poisoning from cheese wrapped in tinfoil. Samples of cheese prepared in this country had been found to be unduly contaminated by the tinfoil in which they were wrapped. The industry was aware of the importance of reducing the contamination to the lowest possible limit, and was making efforts to achieve this end. The matter was being kept under observation.

Sterilization of Mental Defectives.—Mr. GREENWOOD told Mr. Sorensen on December 18th that twenty-one local authorities had endorsed resolutions in favour of an investigation into sterilization in relation to the mentally unfit, but the issue was not one which could suitably be made the subject of a separate inquiry.

Small-pox in London.—Mr. GREENWOOD, replying to Mr. Cadogan, said that during the two weeks ended December 13th, 1930, seventy-five cases of small-pox were notified in the county of London. These figures were provisional, and the cases notified were all of the mild type. There had been no fresh outbreak in London, the disease having been prevalent in the metropolitan area for some considerable time.

Advertisements of Medicated Wine.—On December 15th Mr. HASTINGS asked the Postmaster-General whether his attention had been called to the fact that advertisements for Hall's wine were contained in books of stamps sold at post offices; whether, in view of the fact that this wine contained a large percentage of alcohol and could only be retailed by those holding a licence, and that it was without medicinal value because the small quantity of meat juice it contained is rendered inert by the action of the alcohol in it, he would take steps to see that such advertisements were no longer accepted Mr. LEES-SMITH said that, in accordance with the Government's general decision, no advertisement of alcoholic liquor was now accepted for inclusion in Post Office books of stamps, and this decision applied to advertisements of Hall's wine. Any such advertisements appearing in stamp books now on sale represented issues printed before the decision took effect. Replying further to Mr. Hastings, Mr. Lees-Smith said that the decision referred to was taken two or three months ago. It did not apply to contracts for advertisements which still had to run, perhaps for several months. These advertisements had now run out.

Notes in Brief

The appropriate number of days for which sickness and disablement benefits were paid under the National Health Insurance Acts in Great Britain during each of the years 1927, 1928, and 1929 was 203, 178, and 196 million days respectively.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on December 19th, 1930, the following medical degrees were conferred:

M.B., B.CHIR.—D. W. Bawtree, A. T. Curnow, W. R. H. Pooler.
M.B.—S. E. F. Gooding, W. E. Mashiter.
B.CHIR.—D. G. Macdonald, F. G. Booker.

The following candidates have been approved at the examination indicated:

THIRD M.B.—(*Part I, Surgery, Midwifery, and Gynaecology*): G. L. Alcock, P. T. Ashby, C. P. Bailey, J. S. Barker, W. D. Bell, F. K. Boston, L. V. O. Brown, W. D. Brown, H. S. Buckland, D. C. Carroll, C. L. Collins, J. G. Connell, E. J. Currant, A. Cursham, J. H. Cyriax, E. M. Dimock, D. Divine, A. Eckford, W. A. Fell, F. H. Finlaison, G. H. Gange, G. H. A. Graetz, G. N. Grose, G. D. Kersley, C. R. T. Lane, T. C. Larkworthy, D. L. Lewis, J. W. S. H. Lindahl, E. H. W. Lyle, D. G. Macdonald, D. B. McGavin, F. H. Morrell, W. M. Niblock, W. R. Parkes, M. G. L. Perkins, J. Petro, W. H. Poole, J. Richardson, M. A. Robertson, M. A. Rushton, W. W. Sargant, P. G. Scott, R. P. W. Shackleton, J. Sowerbutts, J. H. Spence, T. C. Stamp, J. W. Summerhayes, C. E. Taylor, A. R. Thomas, E. D. Ward, J. N. Warren, A. M. Weston, J. C. G. Whitelaw, F. J. Wright, C. H. Wrigley. *Women:* C. A. Grove, R. M. W. Turner. (*Part II, Principles and Practice of Physic, Pathology, and Pharmacology*): C. Arthur, H. B. Bagshaw, C. O. Barnes, J. H. Beilby, J. H. Conyers, R. M. S. Cross, E. M. Dimock, D. Divine, W. S. Dyson, F. H. Finlaison, M. S. M. Fordham, E. D. Forster, J. H. Hall, C. J. K. Hamilton, J. O. Harrison, W. V. Howells, G. H. Jennings, J. J. Keevil, H. D. B. Kelly, W. A. Nicholson, G. L. Ormerod, P. H. L. Playfair, V. H. Riddell, N. H. L. Ridley, M. E. D. Roberts, M. A. Robertson, G. Rocyn-Jones, R. H. B. Snow, D. J. R. Steen, E. S. Stern, H. Taylor, B. C. Thompson, J. W. P. Thompson, W. R. Winterton, F. J. Wright. *Women:* A. B. Field, G. E. Grove, E. M. P. Smith.

The election to the Downing Professorship of Medicine has been ordered to be suspended until March 31st next.

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

M.S.—(*Branch I, Surgery*): D. S. M. Barlow, R. H. Boggon (University Medal), M. A. Paul, R. F. Phillips, S. M. Power. (*Branch IV, Laryngology, Otology, and Rhinology*): R. J. Cann (University Medal), W. A. Mill.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—(*Part I*): Margaret F. Coveney, A. W. R. Eardley, J. E. Edson (Distinction in Public Health); T. A. Hunt. (*Part II*): C. England, A. Spencer.

UNIVERSITY OF BIRMINGHAM

At the congregation of the University of Birmingham held on December 19th, 1930, the following medical degrees were conferred:

M.D.—F. Smith.
M.B., CH.B.—R. H. Fooks, C. E. Moorhead, J. V. Walker.

UNIVERSITY OF EDINBURGH

A graduation ceremonial was held on December 19th, 1930, when the folliwing degrees and diplomas were conferred:

M.D.—‡R. D. Aitken, ‡L. J. Davis, I. B. Ewart, †W. M. Ford-Robertson, W. Goldie, ‡Laura M. Ligertwood, J. H. Loots, D. P. MacIver, †M. Sokolovitch, J. Weinstein, *J. H. Harley Williams, M. Witkin.

M.B., CH.B.—J. W. Bridgman, R. O. Cairns, J. G. Craven, W. R. de Faria, W. Finlay, K. N. Flint, M. E. Gazaverli, F. M. Gordon, ‖I. D. Grant, M. B. Griffith, J. R. Hope, J. E. Ilbery, E. Joffe, T. M. Khan, R. S. Kirk, G. Lang, E. H. Langschmidt, Amelia N. Laws, J. Levin, B. P. Lubbe, D. M. Lyon, A. P. M'Ara, D. C. MacGilchrist, D. J. MacRae, C. L. Maingay, H. C. Maingay, D. H. Malherbe, R. A. Mitchell, D. S. Napier, W. G. Pennington, W. M. Phinney, C. M. Ross, N. Shapiro, W. S. Shaw, Edith Simpson, H. Stange, D. Stern, D. W. Taylor, Gertrude J. K. Turner, R. A. Turner, I. D. C. Veitch, F. A. Viapree, C. B. Watson, E. S. Wyder.

D.P.H.—C. P. Beattie.

*Awarded gold medal for thesis.
†Highly commended for thesis.
‡Commended for thesis.
‖With honours.

The Ellis Prize in Physiology has been awarded to W. A. Bain.

NATIONAL UNIVERSITY OF IRELAND

UNIVERSITY COLLEGE, DUBLIN

The following candidates have been approved at the examinations indicated:

M.D.—M. J. Bryson, V. C. Ellis, M. J. O'Neill.
M.D. IN MENTAL DISEASES.—F. L. McLaughlin.
M.CH. IN OPHTHALMOLOGY.—F. J. Lavery.
M.B., B.CH., B.A.O.—*M. Moriarty, *F. O'K. Craven, C. P. B. Bermingham, L. Dunne, J. J. Groome, R. Dunphy, M. J. C. Lynch, N. J. McGahon, P. A. McGuinness, T. J. Martin, T. A. Moynihan, P. O'Driscoll, Johanna O'Shea, §B. de Burca, ‖Mary I. Brennan, ‖Elizabeth M. R. Clarke, ‖Kathleen E. Murphy, ¶J. O'K. Bryson, **M. O'Reilly.
D.P.H.—†P. J. Deery, ‡M. M. J. Maughan, P. Keane, J. C. A. Liddy, J. O'Gorman, Margaret M. Partridge, J. J. Ryan.

*Second class honours.
†First class honours, Part II.
‡Second class honours, Part II.
§Exempted from further examination in Pathology.
‖Exempted from further examination in Part I (Medicine and Pathology).
¶Exempted from further examination in Part II (Surgery, Ophthalmology, and Midwifery).
**Exempted from further examination in Pathology and Part II (Surgery, Ophthalmology, and Midwifery).

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following candidates have been approved at the primary examination for the Fellowship: J. Conroy, F. F. Quigley.

CONJOINT BOARD IN IRELAND

The following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—P. J. Doyle, E. R. Duggan, R. J. Randall, C. J. C. Wilson.
D.P.M.—H. T. Kirkland.
D.P.H.—A. Doherty.

Medical News

The second half of the session 1930-31 of the Medical Society of London opens on January 12th with a pathological meeting. The following discussions have been arranged: January 26th, medical and surgical uses of diathermy, opener Dr. E. P. Cumberbatch; February 9th, the choice of anaesthetic, Dr. I. W. Magill; February 23rd, the treatment of indolent ulcers of the leg, Mr. A. Dickson Wright; March 9th, the treatment of pneumonia, Lord Dawson of Penn; March 23rd, growth in children, clinical, radiological, and histological, Dr. H. A. Harris and Dr. H. H. Mills. The Lettsomian Lectures, on the spleen, its structure, functions, and diseases, will be delivered by Dr. J. W. McNee on February 16th and 25th and March 4th. Sir John Rose Bradford will deliver the annual oration on May 11th. The annual dinner of the society will be held at the Trocadero Restaurant on Friday, March 6th.

Dr. Alfred Adler of Vienna will give an address at a meeting of the Medical Society of Individual Psychology, to be held on Friday, January 16th, at 8.30 p.m., in the rooms of the Medical Society of London, 11, Chandos Street, W.1. All members of the medical profession will be welcome on presentation of their card.

At a meeting of the Pharmaceutical Society of Great Britain, to be held at 17, Bloomsbury Square, W.C., on Tuesday, January 13th, at 8.30 p.m., Professor E. F. Armstrong, F.R.S., will give a lecture entitled "Thoughts from a chemist's garden," in which plant colours, their meaning, interrelationship, and synthesis, will be discussed.

The sixth International Congress of Military Medicine and Pharmacy will be held at The Hague from June 15th to 20th next, and not at Budapest, as erroneously stated in last week's *Journal* (p. 1088). The subscription is 10 Dutch florins for members of the congress, and 5 florins for those who accompany them. Specially reduced railway and steamship fares will be available. Communications from those in Great Britain who wish to attend should be addressed to Major A. D. Stirling, the War Office, Whitehall, S.W.1.

The Anti-Opium Information Bureau, Geneva, announces that "An examination of the principal methods suggested for limiting the world manufacture of narcotics," presented in its Reference Document No. 1, has been issued by the Secretariat of the League of Nations in the form of Document O.C. 1278, dated November 24th, 1930.

A circular has been issued by the London County Council describing the facilities afforded by the London Ambulance Service and giving instructions for obtaining its help. Details of the conditions and circumstances in which ambulances are supplied by the Council free of cost for conveyance to hospitals or private residences, and to the Council's hospitals for infectious and non-infectious diseases, are enumerated in the circular, which also contains particulars of the prescribed charges for the transport of private patients within and beyond the administrative county of London. Explicit directions for calling an ambulance or ambulance omnibus by telephone, telegram, or letter are clearly set out, and a convenient list is given of ambulance stations and addresses. Medical practitioners in London who desire to have a copy of the circular should apply to the medical officer of health for the metropolitan borough in which they practise.

The second International Congress of Sanitary Technique and Communal Hygiene will be held at Milan from April 20th to 26th. Further information can be obtained from the general secretary, Piazza del Duomo, 17, Milan.

We have received from Dr. Ross Mitchell, Editor of the *Manitoba Medical Bulletin*, an illustrated pamphlet, reprinting articles on Canada, Manitoba, and Winnipeg, prepared for the Ninety-eighth Annual Meeting of the British Medical Association, which appeared last year in our own columns and those of the *Canadian Medical Association Journal*. It is dedicated to Dr. A. D. Blackader, "whose enthusiasm, inspiration, and generosity made this work possible."

According to the monthly epidemiological report of the Health Section of the League of Nations, the number of cases of cerebro-spinal meningitis reported by sixty countries has declined from 17,180 during the period July 1st, 1928, to June 30th, 1929, to 16,165 during the period July 1st, 1929, to June 30th, 1930; but at the same time the number of cases increased in fourteen countries, and very markedly in some of them—namely, Lithuania, Algeria, the Sudan, Mexico, and Java. In 1929 the countries most affected by lethargic encephalitis were Denmark (3.9 cases per 100,000 inhabitants), Scotland (3.2 in the towns), England and Wales (2.6), Sweden (2.2), and Czechoslovakia. Outside Europe the morbidity was 1.7 for New Zealand and 3.2 for Japan.

Professor E. W. Hope has written—under the title *Health at the Gateway*—a history of the administrative developments affecting the public health of the city and port of Liverpool, and the questions of international hygiene associated with it. It will be published shortly by the Cambridge University Press.

A quarterly review of medicine, pharmacy, and veterinary medicine is published at Belgrade, under the editorship of Surgeon-General J. T. Staitch, director of the medical department of the Jugoslavian Army. All the original articles are summarized in French, and in English or German, and the various topics are dealt with from the practical standpoint. Interesting illustrations are numerous, and the periodical is a valuable contribution to medical literature.

The annual dinner of the Birmingham Dental Students' Society was held in the Queen's Hotel, on December 13th, 1930, the president, Mr. A. G. Clendinnen, being in the chair. The president of the Birmingham Dental Hospital proposed the toast of the society, and the dean of the hospital, in replying, expressed the hope that the Birmingham Dental School might be moved in the near future to the new hospital centre at Edgbaston. The dinner was well attended, and a large number of old students were present.

We are asked to say that a reunion dinner of the "Rough Riders" (City of London Yeomanry) will be held on January 8th. All who have ever served in the regiment are invited to attend. Tickets can be obtained from G. W. Cheesman, Markmerrow, The Ridgeway, Guildford.

Dr. Olive Robertson Watson of Edinburgh has been appointed by the Secretary of State for Scotland to be a member of the Board of Trustees for the National Galleries of Scotland, until March 31st, 1932.

The centenary of the birth of the celebrated syphilologist Alfred Fournier will be celebrated on May 12th, 1932, under the presidency of Dr. Lucien Hudelo, president of honour of the French Society of Dermatology and Syphiligraphy. Further information can be obtained from the general secretary, Dr. Sicard de Plauzoles, 44, Rue de Lisbonne, Paris, VIII^{e}.

The Swedish gold medal for physical education, awarded by the Swedish Gymnastic Federation, was presented to Dr. Philippe Tissié at the International Ling Congress, recently held at Stockholm.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (*Advertisements, etc*), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Nail Biting

"M.B." asks if any reader can indicate a satisfactory method of preventing children from biting their nails.

Iridocyclitis after Actinotherapy

DR. I. FLACK (Radcliffe, nr. Manchester) writes: I should much like to hear if any of your readers interested in actinotherapy are aware of cases where exposure of the eyes to the light from a mercury vapour lamp has resulted in an attack of acute iridocyclitis. Conjunctivitis is, I know, common enough; but I know of one case where the more serious effect followed careless exposure. At least, that was the only cause which could be suggested after a careful elimination of all other sources—infective or otherwise.

Diabetes in Coal Miners

DR. LEON COLLINS (Sunderland) writes: I have been in practice in a colliery district for seven years. In this period I have had numerous cases of diabetes mellitus in miners' wives, but not one in a miner. I should be interested to hear of other colliery practitioners' experiences, as it would appear from my experience that working among coal dust seems to give immunity from this condition.

Pruritus with Jaundice

MR. ALEX. E. ROCHE (London, W.1) writes: "W. F. T. A." asks for suggestions which would help him to alleviate an intolerable pruritus arising from a progressive jaundice due to carcinoma of the head of the pancreas in a woman, aged 60. He says that "all the usual methods have been tried, but without success." What are these methods? I know of only one—cholecysto-gastrostomy or duodenostomy—invariably successful, whatever the issue, in alleviating such pruritus, and, in the event of survival, in remedying the causative jaundice. Apart from operation, is not morphine the handmaid of euthanasia? Sometimes, of course, the "carcinoma" turns out to be a chronic pancreatitis.

Income Tax

Assessment of Army Officer's Pay, etc.

"B. L. E. D." has been serving as an officer in the Army for three or four years. In 1928-29 and 1929-30 he was serving abroad, and received a "colonial allowance" in addition to his pay. For 1930-31 he is assessable as a resident in the United Kingdom, and has been assessed on the basis of the previous year's income, to include the colonial allowance, which he no longer receives.

*** By the Finance Act of 1927, Section 45, the current year's basis, up to then applicable to earnings assessable under Schedule E, was displaced by that of "the year preceding the year of assessment." But there were three provisos; the second of which was to exclude from the change "the case of any office or employment held occasionally or intermittently in the United Kingdom by a person who is not continuously resident there." We understand that our correspondent was unmarried until his return to this country, and presume that he did not maintain a residence here during his absence. If so, it seems to us that he can fairly claim to bring his case within the proviso quoted, and therefore be charged for 1930-31 on the basis of the current year. We suggest that he puts this point to the authorities, and asks them to state on what ground he is excluded from the relief afforded by that proviso.

LETTERS, NOTES, ETC.

Quinine and Malaria in England

DR. F. WILLIAM COCK (Appledore, Kent) writes: I notice the various communications on the history of the cinchona tree. I was largely brought up in this once most malarious district of Romney Marsh. In fact, I had the benign form of tertian off and on till I was over 30. In my young days there was hardly a house where there wasn't a case to be found at some time of the year. The local practitioners attribute the absence of the disease to the use of quinine. Be that as it may, you will have to search very closely to find a case of ague nowadays. Quinine was introduced into this district about 1850. First Pelletier's, the brownish-coloured drug, and then Howard's. When first introduced the price was a guinea a drachm, or £8 an ounce, very much on the same lines as that of cocaine, of which I took a 2-grain tube into Jersey in 1884 or 1885, the price being 15s. Reverting to ague, it was well known that here and there was a person who was immune, and that also there were people for whom quinine was no good, though bark was. The method was to infuse an ounce of bark in a pint of hot old and hardish ale, and then drink the whole at a draught and lie quiet in bed between the blankets. Of course, port wine and bark in my young days was still taken in this neighbourhood by those who could afford to pay for the menstruum. A good deal of opium was also consumed by malarious people. I remember the old ladies coming into the local grocers' and asking for "fourpennyworth of *gum lodly*"—that is, gum opium, the *lodly* being the local pronunciation of laudanum. They would get a piece about as big as a hazel nut, and they kept a thumbnail the right length which, when filled from the lump, was the right dose. Liquor arsenicalis was always tried when quinine failed to cure. In my time, from about 1868 to 1880 or later, quinine cost 13s. to 15s. an ounce. Since then I have bought it at 1s. 1d. In reading old medical histories one sees that cinchona was almost looked upon as a panacea, and to "throw in the bark" in desperate cases, and in cases of slow convalescence, was the common custom. Need I say I am old enough to have been brought up in that tradition, and still have a fair amount of faith in its application?

Nocturnal Incontinence in Children

DR. T. W. ROTHWELL (Sedbergh) writes: A boy at a preparatory school was brought to my notice as suffering from nocturnal incontinence. The boy seemed otherwise healthy. With small doses of bromide the trouble improved, but not completely. Discussing the boy's appetite with the matron one day, I found that he took large quantities of mustard with his midday meal, even to putting two teaspoonfuls in his soup. We decided to stop the medicine and see what happened. The bed-wetting began again at once. Then we stopped the mustard. The nocturnal incontinence stopped immediately. After fourteen days the boy was allowed the free run of the mustard pot for one day. The same night his bed was soaked. I have since traced two other cases to similar causes, in one case excess of pepper.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 50, 51, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52, 53, and 54.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 7.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 Senile Pulmonary Tuberculosis

U. MASUCCI (*Il Morgagni*, November 2nd, 1930, p. 2079) states that in spite of the studies of Charcot, Peter, Bertolotti, Hirtz, Etienne, Potain, and others, it is still generally supposed that tuberculosis is a disease almost entirely confined to youth. In reality, however, pulmonary tuberculosis not unfrequently develops in an insidious and protracted manner even in advanced life, as illustrated by a case seen by Masucci in a man aged 79, by Sabatini in one of 85, and by Bozzi in one of 108. According to Goglia's statistics of necropsies, senile tuberculosis escapes recognition during life in 68 per cent. As regards the general symptoms, the characteristic tachycardia and arterial hypotension are absent owing to the existence of arterio-sclerosis, which gives rise to hypertension and bradycardia. A rise of temperature at night, one of the most important symptoms of early pulmonary tuberculosis in young patients, is completely absent in a large number of cases, and slight and inconstant in others. Night sweats in old age are even rarer than fever. Physical examination does not as a rule show any definite evidence of disease, but Masucci has found in several of his cases of senile tuberculosis the following symptoms and signs which are constant in younger persons: the presence of micropolyadenopathy—small round painless glands mainly grouped at the site of the lesion; Boeri's sign—tenderness on pressure over the trapezius on the side corresponding to the lesion; dyspnoea; and recurrent slight haemoptysis. The diagnosis, however, can be established in most cases by the search for tubercle bacilli in the sputum, and a radiological examination of the chest.

2 Mild Small-pox

L. DE JONGH (*Klin. Woch.*, October 25th, 1930, p. 2021) states that during an epidemic of small-pox at Rotterdam and The Hague in 1929 he saw 32 cases of very mild small-pox, including 12 cases of non-eruptive variola in nurses. In non-epidemic times such cases are liable to be mistaken for influenza. Most of the patients had been repeatedly vaccinated, the last occasion being usually two months before they had to attend small-pox cases. The incubation period was shorter than usual, being at most 8 to 10 days, and, unlike the incubation period in ordinary small-pox, was not free from symptoms such as pain in the back, lassitude, insomnia, and sore throat. In view of the fact that these non-eruptive cases of small-pox occurred with one exception in recently vaccinated persons, it may be concluded that the immunity conferred by vaccination takes some months to be sufficiently strong to prevent the disease. There is no doubt that these non-eruptive cases are capable of spreading infection, which is specially liable to be conveyed by coughing. The prognosis of non-eruptive small-pox is usually favourable, but the author records one case in which myelitis developed in convalescence, and proved fatal in two months.

3 Epilepsy due to Compression of the Frontal Lobe

In most cases of essential epilepsy the necropsy reveals no macroscopical, and sometimes even no microscopical, cranio-encephalic lesions. BALTHAZARD and SZUMLANSKI (*Paris Méd.*, November 15th, 1930, p.451) report a case of this disease, non-traumatic in origin, and with no clinical lesion, in which the post-mortem examination revealed the principal cause of the convulsive crises. A man, aged 37, who was addicted to alcohol and suffered from mental debility, had suffered from attacks of vertigo and dizziness since the age of 17. He had been interned in an asylum six times during the previous seven years for chronic alcoholism and convulsive and psychic epilepsy. During each of these terms he had had no convulsions and only occasional attacks of vertigo. On each discharge, however, the crises recurred, due to alcoholic excesses and the cessation of treatment, which had included the administration of gardenal. He was found dead one morning, having probably fallen down during an epileptic seizure. There was a large wound on the forehead, which had bled copiously. Death was attributed to haemorrhage, with pulmonary oedema and asphyxia as contributory causes, but at the necropsy an exostosis, the size of a large almond, was found on the internal surface of the frontal bone; this had caused compression, and was sufficient to account for the epileptiform attacks. No evidence of fracture of the skull, meningeal haemorrhage, or meningitis was found. Alcoholism also played a part in increasing the frequency of the epileptic crises and the severity of the mental symptoms. The osseous tumour was possibly of syphilitic origin, though the Wassermann reaction of the blood was negative.

4 Retention of Urine in Typhoid Fever

L. F. DEFAIX (*Thèse de Paris*, 1930, No. 110), who records five illustrative cases in patients aged from 14 to 35, states that retention of urine is a relatively rare occurrence in typhoid fever, although it is mentioned in all the textbooks. It seems to be most frequent in the first week of the disease, but it may occur at any stage and in any form. Previous disease of the urethra and bladder, such as gonorrhoea, probably plays a part in its production, as does physical or moral strain. Retention of urine does not seem to indicate a particularly severe attack of typhoid fever, except when it appears at an early stage, and therefore does not affect the prognosis. As soon as the symptoms develop an attempt to prevent its continuance should at once be made by the application of hot compresses to the hypogastrium, the administration of opium by mouth or enema, or injections of pilocarpine hydrate (1 cg.) or pituitrin (1 to 2 c.cm.). If these measures fail a catheter should be passed twice a day under rigorously aseptic conditions.

5 The Incidence of Weil's Disease in Holland

J. P. BIJL and G. KORTHOF (*Arch. f. Hyg.*, October, 1930, p. 29), working in the Central Laboratory at Utrecht, have encountered sixty-two cases of Weil's disease during the years 1924 to 1930. The diagnosis was made either on the presence of leptospirae in the blood or the urine of the patient, or on the presence of agglutinins or lysins in the blood. The lowest titre of antibodies that has been considered positive was 1 in 1,000. Of the sixty-two cases, no fewer than forty-one occurred in the months of August to October. The great majority of the cases were reported from the low-lying watery provinces of Holland and Utrecht; sixteen of the patients gave a history of a fall into water or of swimming. Not all waters seem equally dangerous. The water is probably infected from the urine of rats, 20 per cent. of which were found to be carrying *Leptospira icterohaemorrhagiae*. Four epidemics of jaundice were investigated in which typical symptoms of Weil's disease were not forthcoming; in none of them was there any evidence of a leptospiral infection.

6 Vaccinal Splenomegaly in Infants

P. LEREBOULLET and R. WORMS (*Paris Méd.*, November 1st, 1930, p. 400), who record an illustrative case in a child, aged 11 days, draw attention to the occurrence of transient splenomegaly, sometimes of considerable degree, in infants during the first weeks of life, and associated with a vaccinal eruption or cutaneous suppuration which could not be attributed to congenital syphilis. In the presence of a large spleen, therefore, without any other symptoms, in an infant a few weeks old, there is no

justification for suspecting congenital syphilis unless the child has not recently been vaccinated or has not recently had some infection of the skin. It is important that repeated examinations should be made to determine whether the enlargement of the spleen is permanent or only transient, as a chronic enlargement continues to remain a valuable evidence of congenital syphilis. It is noteworthy that, though no previous description of vaccinal splenomegaly in the human subject has been given, enlargement of the spleen was recently recorded by Douglas, Wilson-Smith, and Price in twenty-four out of thirty-six cases of experimental generalized vaccinia in the rabbit.

Surgery

7 Open Operation in Fractures

A. YOUNG (*Annals of Surgery*, November, 1930, p. 838) records the result of his experience of twenty years in the treatment of fractures by open operation and direct fixation. The period particularly under review is that between 1917 and 1927, in which time 1,325 cases were treated, an open operation being employed in 539 cases. Immobilization of the fragments was secured by direct fixation in 229, or 17 per cent., of the cases so treated. In the preceding nine years only 6 per cent. of cases had been treated by direct fixation, thus proving the increasing confidence felt in this method of treatment. Of the 229 cases treated by open operation and direct fixation, 43 were wired, 61 were pinned or nailed, in 108 plating was used, and the remaining 17 were dealt with by combinations of metallic fixation or by catgut suture. The choice of method must depend on the individual case, and must aim at securing the most adequate restoration of function with the minimum risk, and the maximal accuracy in the adjustment of the fragments. The careful disinfection of the skin over a wide area, including and passing far beyond the site of fracture, is stressed; out of the whole series of cases reported, only two suffered from any serious infection. Open operation is advocated, not only for unusual fractures, or in cases of fractures with unusual displacement, but as a routine procedure for a large proportion of fractures of the long bones. In the case of fractures or fracture-separations in the elbow region where there is appreciable displacement, an open operation and direct fixation should be the treatment of choice. It has been found that there was no diminution in the activity and efficiency of the processes of repair, and union has in most cases been accelerated by this method of treatment. Only one case has been observed in which union was delayed, and one case in which it failed. The result of twenty years' experience has been to convince the author that in the treatment of many fractures of long bones an open operative procedure is safe in execution; it affords the most hopeful outlook for the early recovery of function, and the most perfect anatomical restoration.

8 Appendicitis in the Middle-aged

F. S. JOHNS (*Virginia Med. Monthly*, November, 1930, p. 509) states that though appendicitis in the middle-aged is less frequent, it is much more severe than in younger persons. The diagnosis is generally made late, because the disease is of gradual onset and there is a delay in calling in the family physician. According to Beckman, Smith, and Everingham the case mortality between 10 and 50 is only 4.7 per cent., but after 50 it is 23 per cent. At the operation the appendix is often found to be gangrenous throughout. A large proportion of the patients die between the fifth and eighth days after operation with cardio-vascular or renal complications, but the extension of gangrene and phlebitis are responsible for the high death rate. Owing to the danger of cardio-vascular changes, local anaesthesia with ethylene is advisable. When general anaesthesia is not used there is less danger of respiratory complications, and nausea and vomiting are reduced to a minimum.

9 Ganglionectomy

P. G. FLOTHOW (*Amer. Journ. Surg.*, October, 1930, p. 8) emphasizes the increasing importance of sympathetic nerve surgery, and reports a series of fourteen cases treated in this way; the patients were suffering from various diseases, such as Raynaud's disease, Buerger's disease, megacolon, and certain types of chronic arthritis. Three cases of Buerger's disease with associated vasospasm are reported; two were in the upper extremities and one in the lower, while one patient had an associated polycythaemia. Of these three cases, two were very successful, and the third would probably have given a good result had not high intestinal obstruction caused the death of the patient. Chronic polyarthritis deformans responded to sympathetic ganglionectomy in four cases, all of which had been treated unsuccessfully by other means for a minimum of eight years. In each case operation was followed by immediate relief of pain and marked improvement in the arthritis. Amputation pains and brachial neuritis have been cured or greatly relieved when the pain was of sympathetic, not psychic, origin, and three cases are quoted. One case of trifacial neuralgia and one of atypical facial pains have been treated, in the former case by a left stellate ganglionectomy, and in the latter by the removal of the right inferior cervical and first thoracic ganglia; the results were most satisfactory a year after the operation. One case of megacolon and one of spastic colon were entirely relieved by lumbar ganglionectomy. In seven of the fourteen cases a dorsal ganglionectomy was done, using the removal of the second rib and transverse process as the approach; in the other seven a transabdominal approach was used for the removal of the lumbar ganglia. It is suggested that future surgical advances may take place in the realm of the sympathetic nervous system.

10 Anhydraemia in Extensive Superficial Burns

F. P. UNDERHILL (*Journ. Amer. Med. Assoc.*, September 20th, 1930, p. 852) draws attention to the increased concentration of the blood found in cases of extensive burns, and attributes to this the so-called "toxaemia," which is, in his opinion, a misnomer. As a result of this increased concentration, the large blood vessels are not properly filled, so that tissue asphyxiation results. Underhill regards the pulmonary oedema of war gas poisoning as analogous to the outpouring of fluid at the site of a burn of the skin, both phenomena being the body's response to intense local irritation, and both resulting in increased blood concentration. Animal experiments have shown that a burn involving one-sixth of the body surface results in the loss from the burnt area of fluid equivalent to 70 per cent. of the blood fluid in twenty-four hours. If the same physiological conditions apply to man, a burn involving one-sixth of the skin area of a man of average weight, whose total blood fluid would be approximately 5,000 c.cm., might result in the loss of 3,500 c.cm. of fluid in twenty-four hours, though it is possible that the loss may be made good, up to a certain point, by substitution of "reserve interstitial fluid"—an unknown factor. Personal experience has led the author to believe that the concentration of the blood up to 125 per cent. of the normal renders life precarious. The fluid lost from burnt surfaces has been found to be almost identical with blood plasma in composition. Experimental work with animals has shown that the absorption from the burnt area of drugs and dyes is extremely small for the first five days; it is thought that the outgoing of fluid is due to increased capillary permeability, whilst reabsorption is a very slow process. The chloride content of the blood has been found inversely proportional to its concentration—the result of the increased capillary permeability, which allows chlorides to pass out with the plasma; the concentration of the blood can conveniently be measured by haemoglobin estimation. Organic damage to the kidneys is not common, but functional derangements are often found; a specific "toxin" causing damage to the kidney need not be assumed, since increased blood concentration is enough to upset the renal function. During the first

twenty-four to thirty-six hours, when the increase of capillary permeability is greatest, normal saline administration should be continuous; in severe cases, 1,000 c.cm. should be injected immediately by the veins. Acidosis may be combated by sodium bicarbonate, given orally when the patient can swallow. During the twenty-four hours 2,000 to 3,000 c.cm. should be given subcutaneously and 200 to 250 c.cm. of tap water by the rectum every three hours. In all, 4 to 8 litres of water are needed daily; the theoretical danger of "water intoxication" need not be feared, since about 35 litres would be necessary for its production. The local treatment of burns is of secondary importance where shock and anhydraemia are severe, and may safely be postponed till the foregoing general measures have been instituted.

11 Primary Cancer of the Lung

E. RIST and J. ROLLAND (*Ann. de. Méd.*, October, 1930, p. 231), who record 23 cases in patients aged from 18 to 73, in all but two of whom the diagnosis was made during life, state that primary cancer of the lung is no longer a rare condition, as was once supposed. Either it is really more frequent than formerly, or else it is becoming easier to recognize. Of the authors' cases 16 occurred in men, and only 7 in women. In five instances coexistence of tuberculous lesions was found at the necropsy, and in three there was a history or clinical manifestations of syphilis. None of the patients had been particularly exposed to the inhalation of dust. The symptoms are those of pleural effusion or of chronic pneumonia. There is nothing special to note in the dyspnoea, cough, or pain, which vary in degrees in different cases. Metastases were found in the following sites: pleurae (6 cases), glands (6 cases), liver (5 cases), brain (2 cases), skin (2 cases), suprarenals (1 case), kidneys (2 cases), spleen (1 case), bone (2 cases), opposite lung (2 cases), peritoneum and mesentery (2 cases). In twelve instances, however, necropsies could not be performed. The diagnosis was made in all cases by radiological appearances, supported by bronchoscopy in 4 cases and by biopsy of an affected gland, metastatic nodule, or portion of the tumour in 8 cases. All the cases terminated fatally. Radiotherapy was used in 10 cases, with the following results: in two it caused considerable relief of the symptoms; in one the neoplasm broke up rapidly, but symptoms of toxaemia soon developed; and in the rest there was no effect.

Therapeutics

12 Treatment of Inflammatory Conditions with Benzyl Cinnamic Ether

LÉVY-SOLAL, J. JACOBSON, J. DALSACE, and M. PARIENTÉ (*Paris Méd.*, October 25th, 1930, p. 369), as a result of previous satisfactory reports on the efficacy of benzyl cinnamic ether on tuberculous and other lesions, tried this drug in ten cases of salpingitis and report their observations. Daily intramuscular injections of 1 c.cm. were given for twelve days into the buttock region; there followed a rest of ten to fifteen days, after which a new series of twelve injections was begun. The authors state that the lesion generally abates at the end of the second series, but when this does not happen another course is given after the lapse of a fortnight. There is no local, focal, or general reaction, but, if the general condition of the patient is poor, a start should be made with half the dose. They arrange their cases in three categories: (1) bed cases where the drug was used from the very beginning; (2) bed cases where it was tried after failure with the classic treatment; and (3) ambulatory patients continuing their usual occupations, in which cases the drug was employed alone. As the result of treatment they found that pain yielded towards the fourth or fifth injection, especially when it had been continuous. In one case of pain in crises the treatment ended in failure. The lesion itself underwent steady regression. The pelvic swelling decreased; it then appeared as only a fullness, and finally there was no longer discoverable any thickening of fibrous consistence. The authors add that the results are as yet too recent to justify the formulating of any opinion as to the ultimate condition, although some of the cases have remained cured for five months. They claim, however, that the results obtained so far deserve to be noted both on functional and on physical grounds.

13 Local Treatment of Ulcers with Insulin

D. ADLERSBERG and A. PERUTZ (*Deut. med. Woch.*, November 7th, 1930, p. 1905) describe a further series of cases of ulcer treated by the local application of insulin. There are theoretical reasons (based partly on Warburg's work on tissue metabolism) for expecting insulin to aid in the growth of granulation tissue and epithelium, and animal experiments carried out by the authors gave encouraging results. The cases consisted chiefly of indolent ulcers of the leg which had failed to respond to other forms of treatment. Some cases of ulcers due to burns, and ulceration of the cervix uteri, were also treated with success. Many of the patients were ambulatory. Once daily insulin is dropped on to the ulcer surface, which is then covered either with an indifferent ointment or with dry gauze. Stimulation of granulation tissue and epithelialization is usually rapid, though occasionally cases are resistant to treatment. Since some have suggested that it is the acidity of the insulin solution which causes the beneficial results, only neutral, or nearly neutral, solutions were used in this series. Weak acids did not promote healing in the same way. No lowering of the blood sugar was noted in any of the cases, so that the effect of the insulin appears to be purely local.

14 Vaccinotherapy in Acute Articular Rheumatism

M. LOEPER and R. DEGOS (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, October 20th, 1930, p. 1463) consider that no sufficient proof of the bacterial specificity of acute rheumatism has yet been produced. They have made use, for diagnosis and treatment, of vaccines prepared by the Pasteur Institute, or, following its methods, and contrary to American observers (who use filtrates), have found that many rheumatic subjects give positive intradermal reactions to certain vaccines, or, if multiple reactions ensue, show a much stronger reaction to one or two organisms. The most commonly used organisms for preparing the vaccines were streptococci, staphylococci, pneumococci, and gonococci. It was noted that 6 out of 10 cases treated were resistant to sodium salicylate by the mouth or intravenously. The authors obtained good curative results in a majority of the cases treated, and consider that vaccinotherapy is of definite value in arresting the more serious complications of the disease. Some cases showed slight febrile reactions, with exacerbation of joint signs; this was regarded as a favourable indication. When these reactions occurred there was no general leucocytosis, but a relative polynuclear increase, and a slight and precocious eosinophilia, regarded as a sign of acceleration of the curative process. In two cases only was the vaccine alone insufficient to cause regression of the disease; in both there was no marked intradermo-reaction to any of the organisms used. The most constantly good results were obtained with mixed strepto-staphylococcal vaccines; intradermo-reactions to these organisms were the most frequently positive. The authors do not claim that vaccine treatment should supersede the use of salicylates, but they suggest that it should always be tried in salicylate-resistant cases, and as an accessory treatment whenever intradermo-reactions are positive.

15 The Cortical Hormone in Addison's Disease

J. M. BERKMAN and J. LANSBURY (*Proc. Staff Meetings, Mayo Clinic*, October 15th, 1930, p. 292) each report a case of Addison's disease, in both of which beneficial results followed treatment with the cortical hormone of Swingle and Pfiffner. The diagnosis in the first case was made owing to marked progressive weakness, loss of weight, gastro-intestinal disturbance, hypotension, and pigmentation. A subcutaneous injection of 10 c.cm. of

the hormone was given, and a modified Muirhead regimen instituted. After two days' improvement a relapse threatened. Since no more hormone was available, physiological saline solution was injected intravenously, and the regimen was continued. The patient once more improved, but loss of weight persisted. With the advent of more hormone, this was again administered. Definite improvement ensued and has continued. The second patient suffered from dyspnoea, loss of weight, and dizziness, and extreme fatigue and palpitation on the slightest exertion; the marked pigmentation characteristic of Addison's disease was present. Treatment with the hormone was commenced, and 86 c.cm. was given in five days, all but 7 c.cm. being administered intravenously. Little change was noted for two days, but then improvement was shown, the patient's colour becoming much more normal; with the exception of headache, she was feeling well and strong at the time of the report. L. G. Rowntree, also of the Mayo Clinic, states that the results in these cases are typical of those obtained in a group of 7 similarly treated. The treatment is usually effective in five days; the appetite and weight increase, and definite euphoria is experienced. Changes in blood pressure and in the amount of pigmentation follow much more slowly than the relief of gastro-intestinal disturbances. However, these results must be regarded as being temporary, immediate, and due to substitution. Patients with Addison's disease suffer from shock in even very minor operations, and it is hoped that this treatment will be an effective pre-operative measure, as is iodine in hyperthyroidism. The results of these preliminary studies seem to indicate that this hormone is a specific for Addison's disease; if so, the therapeutic response to the hormone affords a new test for this disease.

16 A Cereal Mixture for Children

F. F. TISDALL, T. G. H. DRAKE, and A. BROWN (*Amer. Journ. Dis. Child.*, October, 1930, p. 791) introduce a new cereal of the following percentage composition: wheatmeal 53, oatmeal 18, corn meal 10, wheat germ 15, bone meal 2, dried brewers' yeast 1, and alfalfa 1. The ingredients are ground, mixed, and dried at a temperature of 70° C. for thirty minutes. The mixture will keep indefinitely; it is rich in calcium, iron, and copper. Vitamins A, B_1, B_2, D—from ultra-violet irradiation of the wheat germ in yeast—and E are present in appreciable quantity. The average infant and child consume from one to two ounces of the dry cereal per day. It has been used almost exclusively for the past three months in the Hospital for Sick Children at Toronto. It is no different from the ordinary refined, finely milled cereals as regards its laxative or constipating effect, or in palatability.

Neurology and Psychology

17 Amyotrophic Lateral Sclerosis in Epidemic Encephalitis

Since little reference has been made in the literature to the occurrence of amyotrophic lateral sclerosis in chronic epidemic encephalitis, and as the cause of the former disease is unknown, A. M. ORNSTEEN (*Journ. Nerv. and Ment. Dis.*, October, 1930, p. 369) reports a case in which this post-encephalitic syndrome was observed. The onset was sudden, with all the symptoms of acute epidemic encephalitis—upper respiratory discomfort, asthenia, diplopia, and diurnal somnolence. Within a month after this attack a subacute bulbar palsy developed, the first symptom being thickening of the speech (which was attributed to swelling of the tongue) and dysphagia. The later development of universal myoclonia, affecting all the muscles from the masseters and buccinators to the calves, and of spasticity, is interesting owing to the resulting resemblance to Charcot's amyotrophic lateral sclerosis, and supports the view that infection may be the etiological factor in the latter disorder, at any rate in some cases. The atrophy in the case reported was most marked about the shoulders, arms, and chest, while the spasticity and pyramidal tract signs predominated in the lower half of the body. Lesions of the anterior horns and pyramidal tracts are inferred in order to explain the amyotrophic lateral picture, and the pathological findings by Wimmer in two similar cases are cited in evidence. Lesions of the mesencephalon are considered to be the cause of the universal myoclonia rather than ganglion cell irritation in the motor nuclei of cranial nerves and anterior spinal horns. Ornsteen suggests that amyotrophic lateral sclerosis may be related to an old infection, and reviews the opinions of several authorities as regards the nature and causation of this disease.

18 Acute Delirium in Mental Cases

TRÉNEL (*Paris Méd.*, September 27th, 1930, p. 257) describes an acute febrile delirium of extreme gravity, and often fatal, which is met with in some mental cases, and is confined almost exclusively to women. Ladame has classified the symptoms into three groups: grave disturbance of the general nutritive exchanges with intense cachexia and death in one to two weeks; profound mental confusion and rambling delirium; and generalized intense motor agitation. In the hypertoxic fulminating form the onset may be very abrupt; the patient suddenly shows bewilderment, confusion, incoherence, and violent agitation. Insomnia is absolute and intractable. Urinary symptoms are rare, but either incontinence or retention of urine may be present; constipation is the rule. The heart beats violently, and the pulse is uncountable. The temperature rises rapidly, and the patient dies of adynamia or cardiac failure. Another type also occurs which is insidious, and is ushered in by short or prolonged prodromes. The patient becomes preoccupied, indifferent, and morose, and eats irregularly; after some days or weeks the acute symptoms already mentioned supervene. There are three forms of this type: maniacal, melancholic, and a mixed form with both orders of symptoms. The motor disturbance, which is of a choreiform nature, is a very marked symptom. The most constant and almost the most important symptom is sitophobia, with which is associated a continual expectoration without much salivation. The most frequent complication is parotiditis, usually unilateral and secondary to the buccal infection; this is an almost fatal sign. Obstinate constipation is usual, and a most striking symptom is rapid loss of energy with emaciation. Various causes have been suggested for the high fever. The author believes that it is of central origin, since lesions of the ganglions of the base (the site of the thermic centres) have been noted. The etiology and pathogeny of acute delirium are obscure. Many theories have been advanced, and Trénel suggests that it is of endogenous origin. The fact that the disease is practically limited to the female sex, and the frequent coincidence of metrorrhagia, seems to indicate a direct psycho-sexual correlation. Necropsies almost invariably reveal not only a congestion of the internal genital organs, but also recent haemorrhages, which are sometimes encysted and sometimes diffuse. The pathology is discussed at some length. Treatment is purely symptomatic. For the insomnia, hyoscine or scopolamine is advocated, and for the fever cold sponging. Cardiac tonics (camphorated oil in large doses and sparteine) are usually given. Any struggling with the patient must be avoided as much as possible, and forced feeding with a sound must be resorted to in all cases of persistent refusal to eat. Five illustrative cases are recorded.

19 Vascular Lesions of the Hind-brain

Vascular lesions of the lateral portion of the medulla are generally known as the syndrome of the occlusion of the posterior inferior cerebellar artery. H. MERRITT and M. FINLAND (*Brain*, October, 1930, p. 290) believe, contrary to the general supposition, that the syndrome is fairly common; they record six cases encountered at the Boston City Hospital during the past two years, and very similar to those previously reported. The lesion generally

occurs in arterio-sclerotic subjects, and the age of onset in all but one of the present cases was in the sixth or later decades. The onset is usually fairly sudden, but without loss of consciousness, and all the symptoms can be readily explained by the neurological lesion. Vertigo and dysphagia were present in all cases. Pain in the homolateral side of the face, subjective numbness on the contralateral side, and dysarthria were noted in five cases. Diplopia was detected in four patients, and cerebellar symptoms in three. Intractable hiccough was present in only two cases. The site of the lesion is usually the lateral portion of the medulla with its contained structures—namely, the nucleus ambiguus, spinal fillet, oculo-pupillary nucleus, and the descending tract and nucleus of the trigeminal nerve. More dorso-lateral structures, such as the nuclei of the eighth nerve and the restiform body, are injured by any spread of the lesion. Points in the anatomical physiology of the hind-brain, illustrated by these cases, are discussed. The structures in the median portion of the medulla—namely, the twelfth nerve nucleus, the medial lemniscus, and the pyramidal tract—are not involved, since they receive their blood supply through the anterior spinal artery. Foix, Hillemand, and Schalit have come to the conclusion that most so-called cases of thrombosis of the postero-inferior cerebellar artery are really due to a lesion of the artery of the lateral fissure. The diagnosis is usually simple: conditions to be differentiated are tumours of the medulla, syringobulbia, and osteomyelitis of the temporal bone. The authors state, again contrary to the general opinion, that the prognosis is very good; in time most of the symptoms and signs disappear or improve, with the exception of the sensory changes, which, as a rule, persist.

Obstetrics and Gynaecology

20 Operability in Carcinoma of the Cervix

R. KELLER (*La Gynécol.*, September, 1930, p. 546), discussing the difficulties met in assessing the operability of cervical carcinoma, points out that tumours originating in the vaginal cervix frequently extend along the portio vaginalis to the vaginal wall so superficially as to remain operable for a considerable period. Endocervical neoplasms, on the other hand, are apt to extend deeply along the lymphatic routes, so that at the moment when they become obvious at the external os their operability may already be doubtful. Invasion by the tumour of the paracervical and parametrial tissue and the utero-sacral ligaments is the deciding factor in operability. Infiltration of the broad ligament may be neoplastic or inflammatory, and before operation it is impossible to predict with certainty which variety may be met with, or the extent of the technical difficulties which either will induce. Cellular infiltration, which is a tissue reaction against an invasive neoplasm, may not greatly hinder wide hysterectomy, but that following old-standing inflammation, especially puerperal, may make operation impossible. In certain cases the decision as to the possibility of doing Wertheim's operation can only be made after trial dissection in the broad ligaments. Cystoscopy may show that a tumour is inoperable, but at operation in certain cases with normal cystoscopic report it may be found that inflammatory or neoplastic infiltration of the cervico-vesical or vagino-vesical tissue renders radical hysterectomy impossible. Vesical resections are inadvisable. There is much to be said for commencing the operation in the bladder region; the impossibility of separating the tissue in this region excludes a radical operation. At the beginning of the operation, moreover, the condition of the regional lymphatic glands should be investigated. If they are much enlarged, numerous, and densely adherent to the blood vessels they are neoplastic in character, and operability is unlikely. If in spite of slight enlargement the glands are oedematous, and easily movable on their axis, and if parametrial infiltration is absent or not sufficient to prevent tissue cleavage, a radical operation is not contraindicated. Subsequent examination shows in many cases that they are inflamed and not neoplastic.

21 Foetal Injury by Amniotic Bands

J. GRANZOW (*Zentralbl. f. Gynäk.*, October 25th, 1930, p. 2699) records a case in which the mother of two healthy children gave birth spontaneously during the seventh month to a stillborn child with deformities of both lower limbs. In the left leg a deep circular furrow, the result of pressure by an amniotic band, corresponded with the level of an acute-angled tibio-fibular fracture. The ends of the bones projected through a small circular breach in the skin; callus was absent, but the edges of the wound showed signs of healing. In the right the toes were absent, and had, it is concluded, been amputated at an early date by another amniotic band. The placenta and membranes appeared normal, and there was no history of trauma during pregnancy.

22 Uterine Prolapse

V. S. COUNSELLER and L. J. STACY (*Journ. Amer. Med. Assoc.*, October 4th, 1930, p. 983) report the results obtained by various members of the surgical staff of the Mayo Clinic in the case of 980 patients surgically treated for uterine prolapse and associated conditions from 1920 to 1928 inclusive. Answers to questionaries were received from 89 of them (83.5 per cent.), and satisfactory results were reported in 95.9 per cent. of the entire series. Five types of operation were employed. The modified Gilliam operation of internal shortening of the round ligaments, with vaginal plastic procedures, a combination of operations 1 and 2, is shown to be the operation of choice for patients of the child-bearing period. Satisfactory results were obtained in 88.5 per cent. of the cases in which the Gilliam technique was used. The Kocher abdominal fixation operation is reserved for that group of patients who are past the menopause, senile, and constitute poor surgical risks, and for those who have undergone hysterectomy previously, with prolapse of the cervical stump. Satisfactory results were obtained in 94.8 per cent. of the cases. If the uterus is of normal size and there is a mild degree of prolapse, with large cystocele, and the patient has passed the menopause, the Watkins-Wertheim interposition operation is successfully employed, satisfactory results having been obtained in 96.6 per cent. of the cases. When the prolapse is of marked degree and is associated with large cystoceles, and the women are past the menopause, the Mayo vaginal type of hysterectomy is the operation of choice. It was employed in 81 per cent. of the patients who had passed the menopause, with satisfactory results in 97 per cent.

23 Rapid Accouchement by Method of Delmas

P. DELMAS (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, October, 1930, p. 571) has seen no untoward results at his clinic during four years, and in nearly a hundred cases, following rapid delivery by his method of manual dilatation of the cervix after the intraspinal injection of 10 cg. of scurocaine. He stresses the importance of following the technique originally described and of excluding cases in which the cervix and lower uterine segment are not supple. Unfavourable results, he says, are due to neglect of these points. E. H. ROBIOLIS (ibid., p. 568) has been favourably impressed by the ease and harmlessness of Delmas's procedure in five cases of labour which had commenced spontaneously in eclamptic or pre-eclamptic subjects. He emphasizes the importance of giving an adequate dose of scurocaine, but prefers digital (Bonnaire) dilatation of the cervix to that by the clenched hand. E. BRÉMOND (ibid., p. 565) thinks that the low placental insertion in placenta praevia ensures pliability of the cervix and is particularly favourable for the Delmas technique; he records four cases of placenta praevia in which cervical dilatation, version, and extraction were easy. LAFFONT and SESINI (ibid., p. 541) report trial of Delmas's method of delivery under spinal anaesthesia in cases of transverse presentation with pyrexia and cervical

oedema, placenta praevia, and impacted transverse presentation, as a preliminary to hysterectomy. In the first class of case, which is among those excluded by Delmas as unsuitable for his treatment, dilatation was not secured. In the second class manœuvres were easy, but the patient died from shock and haemorrhage. In the third class a lethal rupture of the uterus may have been present before intervention. The conclusion is drawn that states of haemorrhagic shock and cases of impacted transverse presentation contraindicate spinal anaesthesia. A. FRUHINSHOLZ (ibid., p. 585) followed Delmas's technique in the case of a patient dying near term from tuberculous meningitis. Complete but sleeve-like dilatation of the cervix was obtained within four minutes, and extraction of a living child by version was rendered easy. A tear of the lower uterine segment, however, was noted.

Pathology

24 Miliary Aneurysms of Cerebral Arteries

Since there is much doubt concerning the exact nature of *miliary aneurysms* of the small arteries, especially of the cerebral vessels, W. D. FORBUS (*Bull. Johns Hopkins Hosp.*, November, 1930, p. 239) reports a study of these conditions in several cases. The so-called congenital aneurysms were principally investigated, and only those of the superficial cerebral arteries. These observations have led Forbus to believe that miliary aneurysms of these arteries, and probably of all other arteries of medium size, occur quite independently of any inflammatory process, arterio-sclerosis, or external trauma, and that these aneurysms as such are not congenital malformations. They are acquired lesions arising from a combination of local weakness in the vessel wall, resulting from a congenital defect in the media, and degeneration of the internal elastic membrane, due to overstretching of this membrane. This defect occurs at the point of bifurcation of the vessel. The muscular coat of any vessel develops from a group of mesenchymal cells quite separate and distinct from those which form the muscularis of its branches, and the muscular sheath of the parent vessel develops earlier than does that of its branches. A failure of the two separately developing coats to fuse properly offers the possible explanation of the later observed defect. That the malformation of the artery wall at the point of bifurcation underlies the later development of aneurysms appears to be indicated by certain facts which are enumerated.

25 Diagnostic Tests for Syphilis

R. DE BLASIO (*Ann. de Derm. et de Syph.*, October, 1930, p. 1014) describes Amato's test, which depends on a definite leucopenia (not less than 1,000 per c.mm.) found thirty minutes after the intravenous injection of 2 cg. of mercury biniodide; this reaction is fugitive, and the count must be made not more than thirty minutes after the injection. It depends on the occurrence of haemoclastic shock, and is similar to that obtained in tuberculous subjects after tuberculin administration; the same reaction has been applied in other conditions. In 1929 Gouin and others devised a new specific reaction for syphilis, depending on the recognition, two hours after the injection of antisyphilitic medicaments, of a leucocytosis. By the graphic study of a number of blood counts, Blasio claims to have established that Amato's leucopenia and Gouin's leucocytosis are two phases of the same phenomenon—haemoclastic shock. In 15 cases where both reactions were positive he has searched for other signs of this shock, such as a fall in the blood pressure, and found them present. Moreover, in 5 cases he has examined the Arneth index, and found a shift to the left, and from the findings of other workers he thinks that this phenomenon is probably constant. Among 100 cases of known or suspected syphilis Blasio found that the Wassermann test gave most positives, the Sachs-Georgi the second greatest number, the haemoclastic test the third, and the leucocytosis test the fewest. In cases with clinical evidence of visceral syphilis, the haemoclastic test gave a greater percentage of positives than any of the other reactions. Both haemoclastic and leucocytosis tests were tried in 50 non-syphilitic cases (20 healthy and 30 with other diseases), and it was found that the first gave 10 per cent. of positives, and the second 18 per cent. Blasio concludes that Amato's and Gouin's tests demonstrate different phases of the same phenomenon. The first is more specific than the second, and it is well worth trying when the Wassermann test is doubtful or negative, especially in suspected cases of visceral syphilis.

26 Pasteurellosis of Rabbits

J. R. MORCH and G. KROGH-LUND (*C. R. Soc. de Biologie*, November 4th, 1930, p. 319) record the occurrence of an epidemic among the rabbits and guinea-pigs in the Danish Serological Institute during the years 1925 to 1927. The pathological findings at necropsy were extremely variable; sometimes there was a simple haemorrhagic septicaemia without macroscopic changes; sometimes there were fibrino-purulent deposits on the pulmonary and costal pleura, or on the diaphragm and abdominal viscera; in some animals these deposits had become desiccated; in some, cold abscesses were found in the subcutaneous tissue of the abdomen; and in still others destructive inflammatory changes were observable in several joints. The causative organism was a bipolar-staining Gram-negative bacillus identified as belonging to the *Pasteurellâ* group. A number of strains of *Pasteurella* isolated from rabbits, guinea-pigs, cattle, fowls, sheep, hares, mice, and opossums were subjected to a comparative study. All of them were morphologically similar, and many of them formed two distinct types of colony—one a mucoid opalescent, and the other a non-mucoid transparent, colony. No relation could be established between these different types and the species of animal from which the strain was isolated or the pathological character of the disease to which it had given rise. All strains fermented glucose, fructose, sucrose, mannite, and sorbite; some also fermented glycerin, l-dulcite, l-arabinose, d-xylose, d-galactose, d-mannose, maltose, dextrin, glycogen, and starch. According to the fermentation reactions the organisms could be classified into six groups. There appeared to be no correspondence between the fermentative group to which a given strain belonged and the species of animal it was able to attack. Strains of one type could infect more than one different species of animal, and any one species of animal might be infected by more than one type. In practice, the authors consider that for the prevention of the disease in the laboratory all animals coming in should be quarantined, and their blood tested for agglutinins before being allowed to mix with the normal stock.

27 Estimation of Gastric Function

Certain dyes when injected intramuscularly or intravenously are excreted into the stomach, and attempts have been made from time to time to use this as a test of gastric function. T. JENNER (*Münch. med. Woch.*, October 31st, 1930, p. 1883) has tried to correlate the rapidity of dye excretion with certain definite types of gastric disorder as shown by previous test meal examinations and gastroscopy. After passing a narrow gastric tube and giving a test drink, 2 c.cm. of 1 per cent. neutral red is injected intramuscularly. In normal persons the dye is usually to be found in 15 to 20 minutes, in hyperacidity its appearance is more rapid, and in cases of achlorhydria its excretion may be delayed for an hour or more. In practically all cases of catarrhal inflammation of the antrum, excretion of the dye is much delayed, even though the acidity is normal or high. Generalized gastritis has the same effect, irrespective of the type of gastritis present (hypertrophic, catarrhal, or oedematous), but the delay is always particularly pronounced if the antral region is involved. The presence or absence of an ulcer has little influence on the result of the test. It is concluded by the author that, where achlorhydria is absent, delay in neutral red excretion is evidence of the existence of gastritis.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

COMBINED TREATMENT OF ARTHRITIS

By Chalybeate Waters, Tonic Baths and Extension Appliances.

The Belle Vue Spa Hotel provides accommodation for patients for whom these tonic chalybeate waters are indicated. External treatment by tonic baths, as well as by manipulation and extension and light, is also provided.

Recent analyses of the Belle Vue Spa waters show that they are exceptionally rich in ferrous salts. Samples have been repeatedly examined by the Clinical Research Association.

A new building furnished with Baths and all modern Electrical Appliances for treatment was opened on Saturday, April 26th.

Under expert advice the drinking service of the Belle Vue Spa water is now taken from selected sources in the water-yielding rock, and served fresh at the Spa at a standard strength of 1 grain of ferrous sulphate in one ounce.

For patients who are unable to visit Trefriw and take the water on the spot, it is bottled and exported at the same standard strength for medical use in their own homes.

In suitable cases of arthritis and rheumatic disease Hoefftcke's manipulative and ambulatory extension treatment can be applied.

Mobility and freedom from pain in crippling arthritis of the hip and knee can often be obtained, even after shortening and contraction have occurred. This is effected by the extension appliances, which maintain continuous extension by day and by night. The appliance usually permits the patient to walk, and not only supports the weight but replaces the undesirable state of compression of the leg by one of active stretching.

This method secures:—

(1) Extension without muscle loss, inevitable whilst the patient is kept in bed.
(2) Extension without vascular stasis, which occurs when a joint is kept at rest.
(3) MOVEMENT WITHOUT PAIN.

The result has been a restoration of joint function in many cases which had been regarded as hopeless and incurable. The Spa is under medical supervision and close co-operation is maintained with the patient's own physician.

Further particulars may be obtained at Belle Vue Spa or 7, Harley Street, W.1.

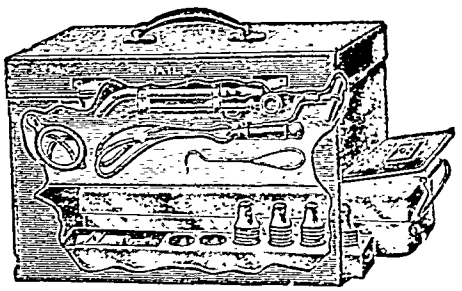
W. H. BAILEY & SON LTD.



S.C. 1360

S.C. 1360.—Bailey's large size Surgeons' Midwifery Case, made in best Cowhide, fitted with Slide Tray, to take six 1-oz. bottles in metal cases, and Chloroform Drop Bottle, in separate compartment at side of Sterilizer.

Size 17 × 10 × 7 ... ... £3 15 0

Ditto, fitted with best nickel-plated stamped-out seamless 16-in. Sterilizer (with lamp and tray) ... £5 15 0

Case fitted complete—Prices on application.

BAILEY'S "BELGRAVE" SPHYGMOMANOMETER

BRITISH MADE THROUGHOUT.

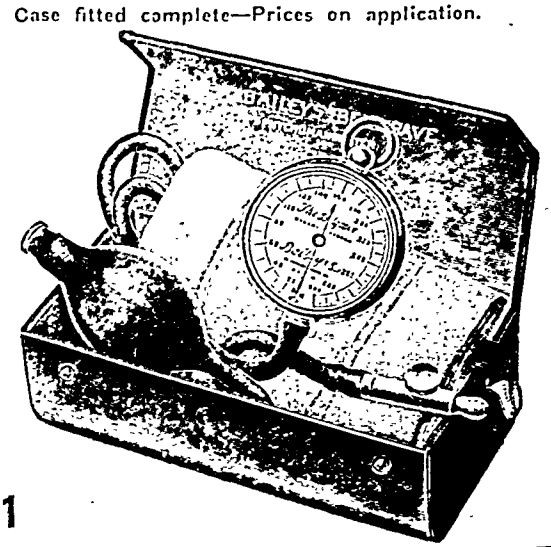
A thoroughly reliable Instrument, accuracy guaranteed. Extremely sensitive. Light and portable.

The Tubes may remain attached to the dial as the interior of the case allows sufficient room to prevent kinking.

An essential Instrument for the General Practitioner

Price - **£2 : 15 : 0**

Post free United Kingdom; India and Colonies 2/6 extra.



Tel. No.: Gerrard 2313 / 3185 — 45, OXFORD STREET / 2, RATHBONE PLACE — **LONDON, W.1**

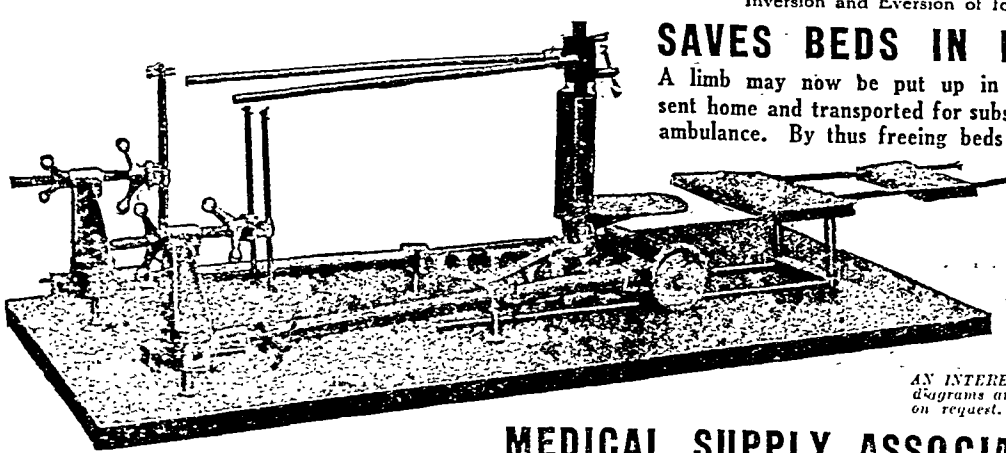
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

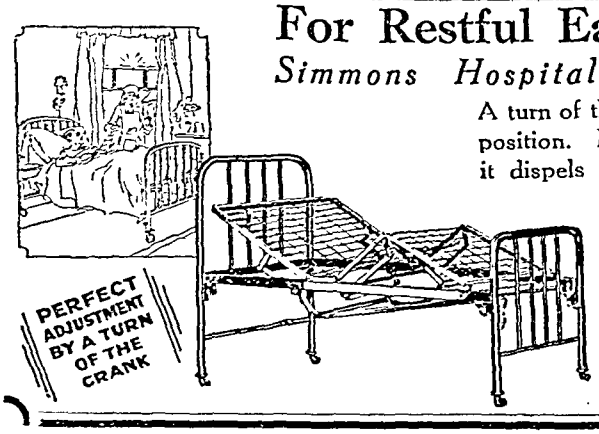
For Restful Ease or Surgical Positions—

Simmons Hospital Beds are instantly adaptable



A turn of the crank adjusts the Simmons Bed into any desirable position. For convalescents this means maximum repose, for it dispels the necessity of constantly rearranging pillows.

The strong construction of Simmons Beds, and their hygienic qualities, make them invaluable to all Hospitals and Institutions.

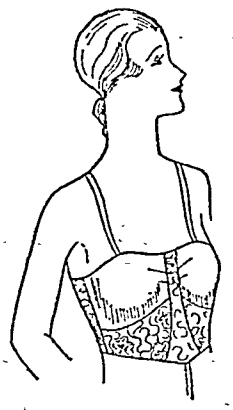
Concerning NODULES OF THE BREAST



"The proper support of the breast, proper instruction, insisting on lack of old constriction, which is quite a common thing among girls who desire to have a boyish figure, has resulted in the disappearance of the lumps in a number of cases."

Concerning PROLAPSE. . . . .

"Prolapse of the virginal atrophic breast is occurring with alarming frequency in this country owing to the present fashion in dress. Uplifting support of the breast will cure the condition if treatment is begun early."

Spencer Uplift Brassieres are prescribed by physicians for breasts that have sagged and lost tone from the wearing of "boyish-form" bandeaux. They are also sponsored by physicians for prolapse of the virginal atrophic breasts; non-malignant nodules of the breast; maternity wear to prevent "caking" and abscess.

Each Spencer Brassiere is designed especially for the wearer. The bust-pockets are fashioned to provide adequate support and positive uplift, even when the breasts are abnormally heavy and pendulous.

The Spencer Corsetière will call at your surgery or patient's home to take measurements under your supervision. If you do not know the address of the local Spencer Corsetière, we shall be happy to supply it on request.

Kaylene

for the treatment of acute intestinal infections, ptomaine and other forms of food poisoning, and all diarrhoeal conditions. It acts by adsorption and is the true antidote to bacterial toxins and toxalbumins in contaminated food.

The action is speedy and certain.

Kaylene-ol

An emulsoid of the toxin adsorbent Kaylene combined with Colonol Liquid Paraffin. The latter counteracts the consolidating effect of the Kaylene. This preparation may be prescribed with confidence for those conditions in which toxaemia is associated with constipation. **It actively prevents the absorption of toxins** and completely puts an end to the fouling of the lymphatics and the blood.

Samples and "adsorption" literature obtainable on request to the Manufacturers:

STANIFORM

Regd. BRAND Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-[illegible] Department and both Nursing Staff and myself were am[illegible] Long-standing, non-healing skin wounds healed after [illegible]

"This is to certify that [illegible] ted with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays"

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments.

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

Telegrams: Castle, Ruthin. Telephone: 66, Ruthin. Ruthin Castle, North Wales.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FACKEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure and farm grounds, and is ready to receive patients. Application can now be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates and in certain cases will be prepared to admit patients free of charge.
Every facility for specialised investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Both certified patients and voluntary boarders are received. Separate houses for treatment and accommodation of special cases adjoin the Institution. There is a seaside branch, Kearsney Court, near Dover, to which patients may be sent for treatment or on holiday. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts. Entertainments, dances, and indoor amusements held throughout the year.
Illustrated prospectus and further particulars can be obtained from the Medical Superintendent.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 66, Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
Formerly Belvoir Nursing Home, Aston-on-Trent.

BRIDGE of ALLAN SPA
Stirlingshire

"THE outstanding features of these waters are the high calcium, bromine and iodine contents. Few waters are so rich in these elements; hence the water gives Bridge of Allan a distinguished place among British Spas.

The waters should command the attention of the medical profession and inspire their confidence wherever a water of such character is required."

—Analytical report by S. Judd Lewis, D.Sc.

For tariff and full particulars apply SPA DIRECTOR

The Allan Water and Spa Hotel adjoins the Spa.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

CRUMPSALL HOSPITAL AND INSTITUTION.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

The Public Health Committee invites applications from qualified Medical Men for the position of Assistant Medical Officer at the Crumpsall Hospital (1,300 beds) and Institution (1,600 beds), including 600 beds for mental patients, Crescent Road, Crumpsall, Manchester.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous hospital experience.

The Hospital is a recognised Training School for Nurses, and is equipped with all modern hospital requirements.

Salary £275 per annum, with board, residence, and laundry in addition. No bonus.

The appointment will be made, in the first instance, for a period of six months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Crumpsall Hospital and Institution," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Thursday, January 15th.

The candidate appointed will be required to commence duty on March 1st, to devote the whole of his time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

F. E. WARBRECK HOWELL,
Town Hall, Town Clerk.
Manchester. December 29th, 1930.

Administrative County of LONDON.

TEMPORARY ASSISTANT MEDICAL OFFICERS.

The LONDON COUNTY COUNCIL invites applications from registered Medical Practitioners (men and women under 45 years of age on January 26th, 1931) for inclusion in the panel for the year 1931-32 for filling vacancies for temporary Assistant Medical Officers for school medical work. The inclusive rate of pay is 30s. a session of 2½ hours, subject to periodical review. Except in special circumstances married women are ineligible.

Special experience of the medical examination of children is necessary. Employment will depend upon the needs of the work, but normally Practitioners will work 3 sessions a week during school terms.

Applications must be made on the official form, copies of which (with full particulars) may be obtained by sending a stamped addressed foolscap envelope to the Medical Officer of Health (S.D.5), The County Hall, Westminster Bridge, S.E.1. Forms must be returned by January 26th. Canvassing disqualifies.

APPOINTMENT OF MEDICAL OFFICER.

I. The Governors invite applications for the above post.

II. The salary will be not less than £750 per annum, with biennial increments of £50 to £1,200.

III. The candidate appointed will be expected to take up his duties on April 27th.

IV. Candidates should be under 45 years of age.

V. They are asked to send in their names, with a statement of their careers and the names of three referees, to the Headmaster, School House, Rugby, as soon as possible, in any case before January 21st. He will be glad to give candidates any additional information that they may require.

City Mental Hospital,

HUMBERSTONE, LEICESTER.

SECOND ASSISTANT MEDICAL OFFICER.

Applications for the above post are invited. Candidates should be single and under 30 years of age.

Salary £350 a year, rising by annual increments of £25 to £450 a year, together with board, lodging, washing, and attendance, valued for the purposes of superannuation at £100 a year.

An allowance of £50 a year will be made in the event of the successful candidate holding a diploma in Psychological Medicine.

Preference will be given to candidates with a University degree who have held a resident house appointment.

The provisions of the Asylums Officers' Superannuation Act, 1909, will be observed.

Applications, marked "A.M.O.," with full particulars of qualifications and experience, together with copies of not more than three recent testimonials, to be sent to the Medical Superintendent.

Harrow Hospital.

RADIOLOGIST.

Applications are desired for the post of Radiologist at Harrow Hospital, where a new X-Ray Unit is to be brought into use in February or March. Suggested honorarium £100 per annum, plus 50 per cent. of the fees from private patients, this being subject to review at the end of 12 months. Applicants must hold the D.M.R.E. Diploma and must be on the staff of a London Hospital. Applications should reach the Secretary on or before January 9th.

Metropolitan Borough of LEWISHAM.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND SENIOR MATERNITY & CHILD WELFARE OFFICER.

The Council invite applications for the appointment of an Assistant Medical Officer of Health and Senior Maternity and Child Welfare Officer from fully qualified and registered Medical Practitioners.

Candidates must have special experience in Infant Welfare Work and Post-graduate experience in Practical Obstetrics, and must possess the qualifications referred to in paragraph No. 6 of the Local Government (Qualification of Medical Officers and Health Visitors) Regulations, 1930, and must also be the holder of the Diploma of Public Health.

The salary will be £750 per annum, rising on approved service by annual increments of £50 to £900 per annum, and actual travelling expenses.

The person appointed will be required to give whole time to the duties of the office, and will be under the administrative control and supervision of the Medical Officer of Health, and will also be required to live within the Borough.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and also subject to three months' notice on either side to terminate the same

Selected candidates will be required to undergo a medical examination.

Applications for the appointment, accompanied by copies of not more than three recent testimonials, must be made on forms to be obtained from the undersigned, and should be received here not later than 4 p.m. on Monday, January 26th.

Canvassing, directly or indirectly, is prohibited, and will disqualify.

JOHN W. SHUTER,
Lewisham Town Hall, Town Clerk.
Catford, S.E.6. December 31st, 1930.

County Borough of Bolton.

A one-half share, with ultimate succession, is offered in a good mixed Practice, averaging about £1,500 p.a., but capable of large increase. Panel of over 1,000. Fees 3/6 to 21/-. Suitable house, with 3 reception, 3 bedrooms, etc. Good garden. Price for freehold £1,500, £1,000 on mortgage. Premium 1½ years' purchase.
5. NEAR FOREST OF DEAN.—Old-established Country PRACTICE, in picturesque surroundings, averaging about £1,250 p.a. Panel of 1,100. Visits from 3/6. Suitable house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £1,500, £1,000 on mortgage. Premium £350 cash, and £1,500 by instalments over five years.
6. NORTH WALES.—Very old-established chiefly middle-class PRACTICE, producing over £800 p.a. Panel of 600. Visits from 2/6, with medicine extra. Very low expenses. House contains 2 reception, 6 bedrooms, etc., and has all modern conveniences. Garden. Garage. Rent on lease £60 p.a. Sport of all kinds and schools. Ample scope for increase. Premium 1 year's purchase.
7. SOUTH COAST TOWN.—Rapidly increasing PRACTICE producing for last 12 months over £400. No panel. Visits 5/- up. Suitable house, with 2 reception, 3 bedrooms, etc. Rent on lease £130. Prem. £600.
8. MIDLANDS.—COUNTY TOWN.—Old-established better-class PRACTICE, averaging £793 p.a. and offering good scope. Panel of 500. Fees 5/- upwards. Well situated house with good garden, with 3 reception, 4 bedrooms, etc. Separate surgery. Rent on lease £111 p.a. Premium 1½ years' purchase.
9. GLOS.—Unopposed very old-established PRACTICE, in beautiful agricultural district, worth over £600 p.a., including appts. of £90 and panel of 480. Very nice house (5 bedrooms, etc.), water laid on, electric light, one acre of ground. Price freehold £2,000, or would be rented. Another smaller house is also available. Premium £750. Good social amenities and scope for increase.
10. SOUTH OF ENGLAND.—COAST TOWN.—PARTNERSHIP.—A share guaranteed to produce £600 p.a. is offered to a suitable man keen on surgery, and pref. holding the F.R.C.S. Rapidly increasing practice, having large scope. Panel of over 1,400. Fees from 3/6. Suitable house can be secured. Premium 2 years' purchase.
11. CHESHIRE.—Coast Town, within reach of Liverpool.—Well-established PRACTICE averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,400, £800 on mortgage. Premium 1½ years' purchase, £1,100 down.
12. SOUTH-WEST LONDON.—Old-established non-panel PRACTICE, having good Ophthalmic connection, and also scope for Ear, Nose, and Throat work. Gross cash receipts for last 12 months over £1,400. Fees 5/- to 2 gns. Midwifery from 5 gns. Good corner house in excellent condition, with ample accommodation. Price for leasehold (with 62 years to run) £1,500. Premium 1½ years' purchase.
13. SOUTH COAST.—FAVOURITE HEALTH RESORT.—Well-established mixed-class PRACTICE, offering good scope. Average gross cash receipts over £700 p.a., including panel of 720. Very good house, with 2 reception, 5 bedrooms, etc. Nice garden. To be sold, or might be let for a time. Premium 1½ years' purchase.
14. YORKSHIRE.—GOOD TOWN.—PARTNERSHIP.—A one-half share (guaranteed to produce £2,000 p.a. in first year) is offered in a good middle-class Practice. Income for the past twelve months approximately £4,000. Small select panel of 430. One appointment worth nearly £650 p.a. Fees 3/6 upwards. Opposition not strong. Suitable house can be bought or leased. Very good educational and sporting facilities. Premium 2 years' purchase.
15. YORKS.—LARGE TOWN.—Old-established middle and working-class PRACTICE averaging £1,778 p.a. Panel of 791. Fees 3/6 to 21/-. Mid. 2 to 10 gns. (about 12 cases yearly). Suitable house, with 2 reception, 4 bedrooms, etc. Separate entrance to professional rooms. Good schools and sporting facilities. Prem. 1½ years' pur.
16. MANCHESTER.—Chiefly working-class PRACTICE. Average income £1,000, including panel of 1,000. Moderate expenses. Corner house, with 3 reception, 3 bedrooms, etc. Garage. Rent on lease £65 p.a. Premium £1,500 or near offer.
17. LANCS.—PARTNERSHIP.—A one-fourth share to commence (with increase up to one-half later) is offered in a very old-established good middle-class Practice producing for the last twelve months over £4,700 p.a. Panel of 2,730. Appts. worth nearly £200 p.a. Visits 2/6 to 12/6. Not much midwifery from 2 to 3 gns. Suitable house obtainable, but, if single, purchaser can reside with Vendor, who is a bachelor. Premium 2 years' purchase.
18. CAMBS.—PARTNERSHIP.—A one-half share is offered in a sound mixed-class Practice, producing last year nearly £2,000. Panel of 765. Situated in pleasant agricultural district, with good sporting facilities. Fees 5/- to 21/-. Suitable house can be rented at £75 p.a. Premium 2 years' purchase.
19. SOUTH-WESTERN COUNTY.—Near the Sea.—Old-estab. easily worked Country PRACTICE, in beautiful district, within reach of Market Town, and averaging £1,100 p.a., including appts. and panel producing £450. Exceptionally attractive modernized house in over 3 acres of ground, with ample accommodation, productive fruit and vegetable garden, with tennis lawn, etc. Water laid on and electric light available shortly. Price, freehold, £3,000, part on mortgage. Premium £1,650. Sport of all kinds and schools within reach.
20. LONDON, S.E.—Outlying Residential Suburb.—Very old-established PRACTICE (hitherto carried on by two men in partnership) is for disposal, or half share would be sold with succession to the whole in 12 months' time. Receipts average about £3,000 p.a., including appts. worth £330 and panel over 1,500. Two houses available. Premium 1½ years' purchase. Eminently suitable for two friends.
21. BORDERS OF NORFOLK AND SUFFOLK.—PARTNERSHIP.—A half-share (with succession in 2 to 3 years' time) in a good mixed unopposed Practice, in pleasant village, near two good towns. Income for last 12 months £1,992, including panel of 1,000, and appts. worth about £150. Fees 2/6 to 10/6. House contains 3 reception, 6 bedrooms, etc. Sport of all kinds. Premium 2 years' purchase.
22. ITALIAN RIVIERA.—SEASON PRACTICE.—Old-established and held by Vendor for the past six years. Average income about £400 p.a. Fees 10/- to 20/- approximately. Suitable furnished flat, with one large reception room, consulting room, 4 bedrooms, etc. Rent on lease £140 p.a. Premium £500.
23. MANCHESTER DISTRICT.—Old-established middle and working-class PRACTICE, worth last year about £700 p.a., including panel of 614 and capable of increase. Expenses small. Well-situated house, with six rooms in addition to professional accommodation. Large garden. Price for freehold £850. Moderate premium accepted.
24. LINCOLNSHIRE COAST.—Well-established mixed-class PRACTICE averaging £2,749 p.a. (last year £2,868) including panel of over 1,700. Fees 3/6 to 21/-. Mid. from 2 gns. (about 70 cases yearly). Newly built modern house, with special professional accom., central heating, etc. Garden. Garage. Price, freehold, £2,300, part on mortgage. Good sport and schools within reach. Prem. 1½ years' pur.
25. PARTNERSHIP. — LONDON, SOUTH-EAST. — Outlying Residential Suburb.—Owing to the retirement of one of three partners the fifth share of an old-estab. Practice is for disposal. Cash receipts average over £5,300 p.a. (last year £5,540), including panel of upwards of 2,000. Visits 3/6 to 10/6. Good house can be rented at £80 p.a. Premium 2 years' purchase.
26. MIDDLESEX.—Rapidly developing district, within 20 miles.—PARTNERSHIP.—A one-half share in an old-estab. good middle-class Practice, averaging for the past two years over £3,500 p.a. The Answer to the "first Question"

INVARIABLY before prescribing for any ailment, the first question the physician asks the patient concerns the function of the bowels.

He then naturally asks himself what corrective, if any, to prescribe to suit the condition, without interfering with the treatment.

Agarol provides a safe answer to this.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is free from any artificial flavouring, sugar, alkali or alcohol. It is safe in diabetes, in gastric diseases, for children as well as adults. No excess of mineral oil to interfere with digestion or to cause leakage.

In addition, *gentle stimulation* of peristalsis, makes the result certain and the re-establishment of regular habits possible.

One tablespoonful at bedtime —is the adult dose.

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

Sales and Service

For the convenience of Medical Men we have organised a Series of SALES and SERVICE WEEKS and will gladly send particulars on request.

WE OFFER MEDICAL MEN THE FOLLOWING SPECIAL FACILITIES:

SALES:

1. A complete range of the latest Models for inspection and trial.
2. The highest allowance for your present Car in part exchange.
3. Special, and strictly private Hire Purchase Terms.
4. Some specially selected Used Cars, guaranteed for Three Months.
5. Our Unique and comprehensive after Sales Service.

SERVICE:

1. We undertake, entirely free of charge, to inspect and test a Doctor's Car, reporting condition in detail.
2. If inconvenient to spare Car between 8 a.m. and 5.30 p.m., we will test and report at any time more convenient; or arrange to loan a Car at a purely nominal charge.

The advantage of having a Car "vetted" before the new season is obvious; and a careful inspection now may lead to the detection and correction of unsuspected faults, obviating serious trouble later.

Consulting Engineers to Medical Insurance Agency of British Medical Association:

MANN EGERTON & Co LTD

Consult us freely and without obligation on any question concerning your Car.

THE CURTIS ABDOMINAL SUPPORT

(Model 1 for average cases. Special designs to meet individual requirements.)

A scientific support exerting a positive pressure which can be measured accurately. Its range, up to 50 lbs., is far more than adequate for all therapeutic purposes.

Unlike other belts which merely limit distension, the Curtis Support supplies a definite thrust in a backward and upward direction which lifts the fallen viscera into place.

The ideal support for *Visceroptosis* of every degree and variety.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,500 copies.

J. & A. CHURCHILL

Purchase now and secure full year's use.

87th Annual Issue. 2,400 pages. 55,000 names. 36s., postage 1s.

The MEDICAL DIRECTORY, 1931

Including Guide to British Spas and Marine Health Resorts, with 14 Pictures of Spas, etc. Edited by R. FORTESCUE FOX, M.D.

"This year, its eighty-seventh annual issue, the Medical Directory contains 2,263 pages, and the names of 55,055 practitioners. It is a volume for which one somehow feels affection, as well as admiration, because of its freedom from mistakes and misprints. The Medical Directory is indispensable and inimitable—an "unofficial" publication to which official publications must give pride of place."
—PRACTITIONER, Jan., 1931.

6 Illustrations. 3s. 6d. Postage 3d.

CHILL: ITS DANGERS AND PREVENTION

By MARIAN THORNETT, F.R.C.S.I.
With a Foreword by Dr. JANE WALKER, C.H., Medical Supt., East Anglian Sanatorium.

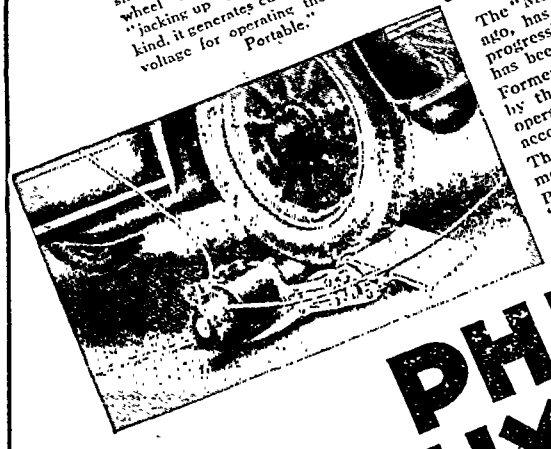
—AND NOW THE "METALIX-PORTABLE" CAN BE OPERATED ANYWHERE

Right—The "Metalix-Portable" in use in a patient's home. There is an entire absence of danger and the outfit can be assembled ready for use in a few minutes.

Below—Philips Auto-Generator shown in position under the rear wheel of a motor-car. Without "jacking up" or complications of any kind, it generates current at the exact voltage for operating the "Metalix-Portable."



The "Metalix-Portable" X-ray outfit, since its introduction over two years ago, has proved an unqualified success. The enthusiasm with which progressive medical men have adopted this additional aid to diagnosis has been little short of amazing.

Formerly confined to districts served by electricity supply companies, by the use of an auto-generator the "Metalix-Portable" can now be operated in the remotest districts—the complete apparatus is easily accommodated in a small motor car.

The "Metalix-Portable" is of *definite interest* to the majority of medical men—a demonstration invariably turns scepticism into enthusiasm.

Please ask your secretary to send a postcard for a copy of the 36-page "Metalix-Portable" brochure.

Price of the "Metalix-Portable" complete for operation on standard A.C. voltages, £138 . 0 . 0; D.C. voltages, £25 . 0 . 0 extra.

PHILIPS METALIX-PORTABLE

The Biological Significance of BOVRIL

BOVRIL combines the nutritive proteins of beef with its stimulant and body-building extractives. The beneficial effect of Bovril upon a weakened constitution is therefore of a permanent nature. It helps the patient not only to gain strength but also to consolidate it.

DISMENOL for instantaneous relief of pain in DYSMENORRHOEA

In spasmodic Dysmenorrhoea the primary call is for the elimination of pain, and the physician has a valuable weapon in Dismenol Tablets, which are entirely *free from narcotics.* This product is a sure and safe sedative in all cases of Dysmenorrhoea, possessing anti-spasmodic properties of a remarkable kind. A feeling of general well-being is substituted for the state of lassitude in the patient.

Please write for samples and literature (also formula) to—

ROBERTS & Co., 76, NEW BOND STREET, LONDON, W.1.

Pharmaciens to H.M. the King.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Write for samples and literature to

Symptomatic relief in 5 minutes

THE symptoms of common cold—congestion, discharge and obstructed breathing—are frequently distressing. From the patient's point of view, they constitute the essence of the annoyance from which he is seeking immediate relief.

Rapidity of action is characteristic of Mistol. Consisting of menthol, camphor, eucalyptol, and chlorbutol in a light oily solution that spreads promptly to all parts of the nasal mucosa, it relieves congestion, reduces discharge and clears the nasal passages within five minutes.

This symptomatic improvement also benefits the pathological state and tends to shorten the duration of the cold. Venous stasis in the mucous membrane is corrected, hyperemia diminished, and over-activity of the secreting glands checked. Repeated instillations of Mistol promote a more rapid return to normal conditions within the nares.

The formula of Mistol is the result of long and careful research, suggested primarily by prescriptions used for many years by leading rhinologists.

Mellin's Food

A MILK MODIFIER

MELLIN'S FOOD is specially prepared for modifying and adjusting cow's milk to meet the nutritive needs of infants deprived of human milk.

No matter whether certified, pasteurised, dried, or condensed milk is employed, its digestibility and its value as nourishment for the baby is enhanced by the addition of Mellin's Food. In other words, milk in any form is better borne, more completely utilised, and its nutritive constituents more appropriately balanced if properly modified with Mellin's Food.

There is no milk modifier exactly like Mellin's Food, and its continued recommendation by a large number of members of the Medical Profession is ample evidence of its outstanding advantages.

Further particulars and samples will be supplied on request.

"MODIFIED MILK IN INFANT FEEDING."

The above-named booklet of 64 pages will be gladly sent to members of the Medical Profession.

MELLIN'S FOOD LTD., LONDON, S.E.15

SELECTIVE GERMICIDAL POWER

STREPTOCOCCUS HAEMOLYTICUS

IT is not generally recognized that antiseptics exhibit wide variations in their power of killing different bacteria. Phenol, the first antiseptic ever used, affords an example of this. It differentiates so markedly between the typhoid-coli group and the Gram-positive cocci that, if added in the proportion of 1 in 200 to a medium inoculated with a mixture of B. coli and streptococci, the former are killed and the latter multiply.

Monsol, which is derived from a by-product of the Mond power-gas process, differs radically from other coal-tar antiseptics in its selective action, which is the opposite of ordinary coal-tar preparations. Its power of killing the STREPTOCOCCUS PYOGENES, and notably the strain HAEMOLYTICUS, is more than 10 times greater than that pure phenol or of lysol.

Monsol is non-irritant, and can be applied in effective dilution even to mucous membrane. In view of these facts it is not surprising that Monsol has been found to have unprecedented qualities in the treatment of Streptococcal infections.

Monsol can be applied to the treatment of septic conditions of the SKIN, the MOUTH and THROAT, and the MUCOSA, and is especially indicated in Obstetrics.

Medisoap Therapy

DISEASES OF THE SCALP.

The use of Medisoaps ensures the proper application of curative agents to the Scalp and at the same time attains its adequate cleansing.

The standard range of Medisoap formulae contains several which are suitable for this purpose.

Those containing Resorcinol in various combinations (Nos. 40, 41, 57 and 71) are almost specific in cases of dandruff and are usually successful in the more serious scalp diseases.

A useful "Prescribers' Index to Medisoaps" will be sent, post free, on request.

For Raising the Resistance to Bacterial Infection

The necessity for an adequate supply of Vitamin A *"to raise the resistance either local or general or both to bacterial infection"* has been demonstrated by exhaustive experimentation *(B.M.J.,* Jan. 1st, 1929, p. 984), and this necessity is now generally recognised and appreciated.

The difficulty lies in the choice of a reliable medium through which to administer the vitamin.

Hence the value to the physician of

RADIOSTOLEUM

with its standardised content of Vitamin A, harmonised with a measured quantity of Vitamin D.

Issued as a highly active liquid and in capsules

OVALTINE

IN GALACTOSIS

Diet in lactation is a matter of no less importance than diet during pregnancy.

"Ovaltine" completely meets the requirements of the diet of the nursing mother by providing adequate and appropriate nourishment.

It is easily digested, wholly nourishing, and does not convey any noxious or unpalatable substances to the breast milk. For these reasons "Ovaltine" will be found a most dependable prescription for establishing galactosis.

"Ovaltine" is recommended to be given about the sixth month of gestation and should be continued throughout the nursing period. A rich milk secretion is thus encouraged and the health of the patient safeguarded against overstrain.

As an example of the nutritive power of "Ovaltine" it may be stated that one cupful yields more nourishment than 3 eggs or twelve cups of beef-tea.

A liberal supply for clinical trial sent free on request.

NEHEBKAU.—*A Serpent Goddess who performed many offices for the dead.*

M 244

The LOGICAL COMPLEMENT to the PHYSIOLOGY of EVACUATION

WHAT MAGNESIA-OIL IS (Musterole Brand) —AND WHAT IT DOES!

An intimate association of Pure Liquid Paraffin with Magnesia in a state of ultra-superfine division, which ensures an unusual therapeutic activity.

M-O is certain but bland in action. It is both laxative and adsorbent, *and promotes cleanliness* throughout the whole intestinal tract.

There are no secondary effects whatever.

CHIEF INDICATIONS

CONSTIPATION — Pregnancy, Infancy and Age
FLATULENCE..ACID ERUCTATIONS
NAUSEA ..... VOMITING
HYPEREMESIS ..... TOXÆMIAS
HYPERACIDITY..... DYSPEPSIA
COLITIS, ETC.

THE Physiology of Evacuation is a very complex affair. A gastro-colic reflex causes transference from the cæcum to the transverse and descending colons; the mass remains at the sigmoid flexure whence portions are passed into the rectum — giving rise to evacuative desire: there follows relaxation of sphincter ani plus contraction of sigmoid and rectal walls, assisted by voluntary contraction of abdominal wall and pelvic floor and the control of the higher centres.

Yet how often there is difficult, or no, evacuation!

The reason usually is that the fæces are of such dense consistency that the whole machinery of evacuation cannot expel them:

The Corrective Complement is:— Prevent the fæces from becoming hard — not by mucosa-irritating purgatives — but by the certain admixture with them of Magnesia-Oil (Musterole Brand). This product ensures a consistent soft stool by its even diffusion throughout the bowel contents. It does not irritate, and it promotes the recovery of intestinal tone so necessary to physiological function.

Send your professional card for clinical sample.

London Agents:

Messrs. SQUIRE & SONS, Chemists to H.M. the King, 413, OXFORD STREET.

On the Absorption of Sanatogen

Why it is that Sanatogen is absorbed with ease even by the weakest stomach.

The tonic influence of the glycero-phosphoric-acid in the chemical combination casein-sodium glycerophosphate (Sanatogen) makes the use of casein possible in cases where the patient has to a great extent lost his capacity of absorption (Tunnicliffe, Tischer-Beddies, Chajes, a.o.).

French authorities (Robin and others) ascribe to the glycero-phosphates a great influence on the utilization of the albumin in the body. The manufacture of Sanatogen is conducted under the strictest scientific control ensuring absolute purity, sterility and uniformly high dietetic value.

Samples and Literature will gladly be sent on request to:

FAMILIARITY BREEDS CONTEMPT

Are we not, at times, inclined to allow practical activities to cloud our perception of the familiar fact, that Dental Caries is an *incurable* disease?

As every doctor knows, this is one of those pathological conditions that show little, if any, tendency towards spontaneous cure, or even arrest, of its ravages.

The only scientific method of combating this affection is through preventive measures. And it is this truth that is the keynote of all Gibbs Advertising propaganda. Care of the teeth, cleanliness of the mouth, are urged as first principles.

In the great national and provincial newspapers; in the most widely read magazines, many millions of Gibbs messages are carried from end to end of the kingdom. And every message can be crystallised in that oft'-repeated phrase: "Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day."

It is in such practical ways as these that Gibbs work hand in glove with Doctors and Dentists — never failing to depict them as the highest and final authorities on all matters connected with the teeth.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

CALCIUM-SANDOZ

$(C_6H_{11}O_7)_2$ Ca.

Unique Advantages:

1.—It is effective. It supplies the physiologically active calcium ion.

2.—It shows distinct superiority in all modes of administration.

ORALLY: It is well absorbed. It is easily administered and does not upset the digestive tract.

INTRAVENOUSLY: It is better tolerated than calcium chloride. The acid-base factor is eliminated.

INTRAMUSCULARLY: It is painless and non-irritating. It is the only calcium salt which can be so administered in adequate doses.

3.—It enables physicians to adequately meet the requirements of any given case.

BY VEIN, for acute need.
BY MUSCLE, to secure intense and prolonged action.
BY MOUTH, for prolonged administration, to meet an increased demand by the organism.

4.—It is completely sufficient in itself as a therapeutic agent.

CALCIUM-SANDOZ is supplied in

Ampoules containing a 10% sterile solution for intravenous or intramuscular injection.
5 c.c. size: Boxes of 2 and 10 ampoules.
10 c.c. size: Boxes of 1, 5, and 20 ampoules.

Powder for oral administration.—Cartons of 2, 4, and 16 ounces.

Tablets for oral administration.—Each tablet contains 25 grains of calcium gluconate and is especially adapted for division into three parts. Boxes of 30 and 150 tablets. Cartons containing 12 boxes of 30 tablets.

Local Anæsthesia in Surgical Practice

CERVICAL ADENITIS.

Typical Case.

The following case will illustrate the application of Local Anaesthesia in Children, in whom the establishment of General Anaesthesia would seem especially harzardous.

B. D., aged 9 months.

Diagnosis: Suppurative cervical adenitis.

Operation: Incision and drainage.

Anaesthesia: Local infiltration, 20 c.c. of a 0.5 per cent. Novocain-Adrenaline solution.

Operation: A direct infiltration was made over the swelling, using 20 c.c. of a 0.5 of 1 per cent. Novocain-Adrenaline solution. The skin was picked up with towel pins to avoid pressure, and a transverse incision was made down to the cervical fascia. At this point the operation was delayed while the cervical fascia was infiltrated. This layer was then picked up with towel pins and a sharp-pointed haemostat was forced through and spread widely, opening the abscess.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

WHOOPING COUGH

Reports on the use of Ephedrine in Whooping Cough are extremely encouraging. Relief from spasm and vomiting occurs in the majority of cases, and in those cases where the cough remains it is of the mild type associated with upper respiratory infection and not characteristic of Whooping Cough.

EPHRETUSS

This is an effective combination containing Ephedrine Hydrochlor. gr. 1/8 in one drachm. Not only do children find it acceptable, but it is particularly useful in controlling the spasmodic coughing and vomiting, especially during the second stage.

Issued in 4-oz., 8-oz., and 16-oz. bottles.

Particulars will gladly be sent on application to:

ANCIENT TALISMAN SEAL INSCRIBED IN ARABIC WITH THE WORDS "MAHOMET GIVER OF HEALTH."

Mahomet himself taught that the best medicine was a sober and temperate life, and he enjoined upon his followers the practice of personal hygiene especially in such matters as cleanliness and diet.

It is very arresting to read the following account of the inauguration of a hospital by the thirteenth century Arabians in their Egyptian dominions: "When the building was finished, Al-Mansur had brought to him a bowl of wine and, drinking, said: 'I have founded this institution for my equals and those beneath me; it is intended for rulers and subjects, for soldiers and for the Emir, for great and small, freemen and slaves, men and women.' He ordered medicaments, physicians and everything else that could be required by anyone in any form of sickness; placed male and female attendants at the disposal of patients, determined their pay, provided beds for patients and supplied them with every kind of covering that could be required in any complaint."

The hospital buildings included a mosque, an orphanage, an academy and a library in which students might read medical works. The date of the seal here reproduced is uncertain.

DATE: A.D. 632 (Death of Mahomet)

Malcolm Morris Memorial Lecture

ON

THE OUTLOOK ON TUBERCULOSIS: CHANGING ORIENTATION

BY

SIR ROBERT PHILIP, M.D., LL.D.

PROFESSOR OF TUBERCULOSIS, UNIVERSITY OF EDINBURGH; PHYSICIAN CONSULTANT, EDINBURGH ROYAL INFIRMARY

We are met to-day to commemorate the life and work of one who was "honoured in his generation—a leader of the people by his counsels, and by his knowledge of learning meet for the people, wise and eloquent in instruction."

The setting of this memorial gathering is remarkable—scenically appropriate. The Chadwick Trust—under whose auspices the meeting is convened—serves as a perennial monument to one whose inspiration "lay in the conception that the life of man is so entirely influenced and affected by its surroundings, that by a perfected sanitary code the death rates may be made, practically, whatever we like to make them, until we arrive at that natural duration of human existence which is bounded by anatomical or physiological law."

Edwin Chadwick stepped into the open as champion for man's heritage of health about the commencement of the Victorian era, at a time when Great Britain was apparently spending little more than £2,000 a year on everything that concerned public health. What a contrast to 1928, when the national expenditure for health measures exceeded £10,000,000, not including national health insurance and medical services to sick poor and school children!

Chadwick's contribution to the renaissance of thought and effort is incalculable. There is no need to dwell, in the presence of the Chadwick trustees, on his incomparable achievements. The chaplet of laurel with which towards the close of his life he was enwreathed by France bore the legend, "*Une des gloires de l'Angleterre.*"

It is likewise fitting—and no less gratifying to many of us—that this gathering in commemoration of one of Chadwick's ardent followers is presided over by the honoured Nestor of the trustees, whose long life of distinguished service has run parallel with the beneficent revolution in the domain of health inspired by the labours of Edwin Chadwick, and who himself has been a foremost exponent and no less striking illustration of the virtues of healthy living. There is fitness, too, let me add, in the fact that the invitations to the meeting have been issued by the daughter-in-law of another valiant warrior in the great campaign.

AN APOSTLE OF PREVENTIVE MEDICINE

Could the central figure in our recollections be with us this afternoon, I believe this *mise en scène* would not be displeasing to him. For Edwin Chadwick and Malcolm Morris were cast in a like mould. They had much in common. They scanned the causes of health and disease with the scrutiny of the statesman. They were not content with the expediencies of the politician. Both observed, pondered, drew their conclusions, and acted firmly and fearlessly.

The town of Goole, where Malcolm Morris practised medicine for nine years, lacked horizon for his vision and scope for his superabounding energy. He needed for his workshop the world of his fellows. There was a supreme purpose in what he said and did. So he came to London, where "nature willed him to wear himself and never rest" until the end.

For our present purpose his life presents two main aspects. In the first place, he made himself master in the department of medicine which he especially professed. He did much to raise dermatology to the position it now occupies in the realm of scientific medicine. His name holds an honoured place in the records of the subject as a learned exponent and trusted physician whose happiness lay in taking infinite pains.

Beyond this, however, he delved deeply among the twisted roots of communal disease. The health of the nation became for him the burden of thought and song. A citizen of the world, he accepted collective responsibility, and showed a keen flair for the abolition of disease by the removal of preventable causes.

It is not my province to dwell on the narrower side of his professional life. His powerful impress, and the impulse he imparted to the study of the skin in health and disease, are reflected on other occasions. We are concerned to-day with his larger objective. Here, his personality had ample scope. He was pre-eminently an apostle of preventive medicine.

MORRIS'S INTEREST IN TUBERCULOSIS

In particular, it is fitting to recall his great interest in the problems of tuberculosis and the effective part he played in attempting their solution.

My first lengthy conversation with him—so far as I can recollect—was in 1897 or 1898. He had heard something of the work at Edinburgh and was attracted by the application of the concerted scheme, which by that date had assumed definite shape. Thus began a friendship which it was my happiness to enjoy until it passed into affectionate regard for his memory. When there came the chance of a long talk with Malcolm Morris there was naturally little reference to dermatology. Whether in Harley Street or at the Reform Club, it was the larger issue. He always had time for that. I recall a delightful meeting with him in Paris in 1905 during the session of the International Congress on Tuberculosis. As we paced its squares and gardens, if his sensitive, well-trained eye was not engaged with some architectural feature on which he dwelt with informed affection, he talked with emphasis and discrimination on what had been achieved, or might yet be achieved, in the campaign against tuberculosis.

In 1898, as editor of the *Practitioner*, he wrote:

"No pestilence which visits mankind makes anything like the havoc that is wrought by tuberculosis; typhoid fever, diphtheria, scarlet fever, measles, small-pox, cholera, and all other infectious diseases together do not claim half so many victims as are killed by tuberculosis. And when, in addition to this enormous destruction of life, there is taken into account the amount of suffering which it causes to the patient, and the expense, trouble, and danger which it entails on those about him, it will be recognized that tuberculosis is one of the worst scourges which afflict the human race. . . . The question is not one of merely philanthropic interest; it is of national importance, as it closely concerns the maintenance of the vigour of the race. On this ground the co-operation of the State might well be asked. In this country it is notoriously difficult to get even enlightened statesmen to attend to anything out of which party capital cannot be made. But even here the day is surely, if somewhat slowly, coming when ordinary legislators will be brought to recognize that the public health is the first and greatest of political questions. Let us, in short, have a national crusade against a national disease."

FOUNDATION OF NATIONAL ASSOCIATION

That same year he was a member of the group which, under the presidency of Sir William Broadbent, focused opinion and effort by the establishment of the National Association for the Prevention of Consumption (afterwards termed tuberculosis). It will be recalled that the

movement gained the sympathy of King Edward VII, then Prince of Wales, who convened a meeting at Marlborough House on December 20th, 1898.

In speaking of the purpose of the association, Sir William Broadbent, as chairman of the organizing committee, said:

"The mission of the association is to carry into every dwelling in the land an elementary knowledge of the mode in which consumption is propagated, and of the means by which its spread may be prevented, and thus to strengthen the hands of medical men throughout the country who are dealing with individual cases of this disease. To this end the public attention must be captured, the public imagination must be impressed, the defensive instincts of the general public must be aroused, and we do not hesitate to express our belief that your Royal Highness will, by the single gracious act of calling together and presiding over this meeting, save thousands of lives."

The resolution put to the meeting by His Royal Highness was as follows:

"This meeting desires to express its approval of the effort which is being made by the National Association for the Prevention of Consumption and other forms of Tuberculosis to check the spread of the disease due to tubercle, and to promote the recovery of those suffering from consumption and tuberculous disease generally. It also commends the method adopted by the association, of instructing public opinion and stimulating public interest, rather than the advocacy of measures of compulsion."

The council of the National Association was then formed, with Sir William Broadbent as chairman and Sir Malcolm Morris as treasurer. Speaking as one of the early members of that council, I desire to testify to the immense impetus given to the association by Sir Malcolm's clear vision and indefatigable energy. It was chiefly owing to him that the great British Congress on Tuberculosis was held in London in July, 1901—a congress attended by medical men from all parts of the world. The discussions covered a very wide field. One of the memorable events was the general address by Professor Koch, in which he made light of the intercommunicability of human and bovine tuberculosis. The criticism which followed at the close of the address led to the institution of the Royal Commission, whose conclusions showed that Koch's view was not justified by the facts.

In the annual report of the National Association (March, 1903) special emphasis was laid upon the splendid services rendered by the honorary treasurer, Mr. Morris.

"He had acted as honorary treasurer-general to the International Congress and had borne the brunt of the great labour entailed. The success of the Congress and the admirable character of all the arrangements connected with it, afford an abiding testimony to his ability, energy, and public spirit."

VALUE OF CONCERTED EFFORT

I have vivid recollections of his timely and gallant aid when he spoke in Edinburgh in 1904 as medical president of the Fourth International Home Relief Conference. It was a time when there was still a good deal of cold-shouldering, a time of cross purposes and cross currents, when proposals were followed only by counter proposals. The opportunity was afforded by the international conference of restating the purposes and methods of the co-ordinated scheme against tuberculosis which, begun in 1887, was gradually becoming known as the Edinburgh scheme. As president, he formally seconded the following motion, which had been submitted by me to the congress:

"That, in the opinion of this Section, organized effort against tuberculosis is required. The Section believes that this would be effected by the establishment of properly equipped dispensaries under the direction of the municipalities or local authorities."

He added that, in his opinion, tuberculosis stood absolutely by itself; it was one of the diseases of which they knew the cause, and it ran a peculiar course.

"They desired to carry out an organized scheme against it and wanted the officials of the country to assist them. By passing this resolution the Section would strengthen the hands of the authorities. No Act of Parliament would ever come into force unless the authorities felt that public opinion demanded it. No President of a Board would initiate anything unless it should come from the public themselves. He put the resolution before them in order that, by passing it, they might strengthen the municipal authorities, not oppose them, in order that they might in this way express to the authorities their opinion that the time was ripe for action. He did not believe it would have been right to pass such a resolution five or six years ago; it was only the result of the experience of the work . . . that had advanced the movement in spite of checks."

His very practical appreciation of the possibilities of the concerted tuberculosis scheme was conspicuously illustrated by remarks which he made on the occasion of the semi-jubilee of the tuberculosis dispensary at Edinburgh in 1912. In conversation he led me to understand that, behind the scenes, he had pulled all his weight for the appointment of the Departmental Committee on Tuberculosis which, it will be remembered, led finally to the adoption of the national pattern of co-ordinated tuberculosis schemes.

NATIONAL TUBERCULOSIS SCHEME

It is not my purpose to dwell on the developments which have followed since the adoption of a uniform tuberculosis scheme for this country. It is sufficient to recall that, while thirty years ago there were not more than two or three sanatoriums in Great Britain, and only one tuberculosis dispensary, there now exist in England and Scotland, approved by the central health authorities, more than three hundred sanatoriums and hospitals, and some five hundred tuberculosis dispensaries. This means that, under the direction of every local authority in the kingdom, machinery is in operation for the detection of tuberculosis at an early date, for the improvement of environmental conditions in the widest sense, for the treatment of the various forms of tuberculosis with a view to cure, and for the segregation and hospital care of more advanced cases.

This very remarkable fact illustrates the extraordinary change of outlook which has occurred with regard to the whole subject. It is the more remarkable when we consider that the formal recognition of the nation's responsibility was achieved only eighteen years ago, and that initial efforts to erect appropriate machinery all over the country were abruptly interrupted by the outbreak of the war, the immediate and later effects of which have proved disastrous in this as in other fields. Accordingly, as was inevitable, the machinery is not all it might be in various ways, and its quality is far from being uniform throughout the kingdom. Both the machinery and the personnel in charge stand to be improved. None the less, we have already attained, as in no other country in the world, a uniform, concerted scheme, functioning more or less adequately in every part of the land. The fact registers effectively the amazing alteration of national outlook.

RETROSPECT

What need of further illustration of the change in thought and action? And yet—because the immensity of the change in methods and results is still hardly realized—I am tempted to cite a witness whose testimony regarding the outlook in the past is no less true than picturesque. Sir Clifford Allbutt, whose birth coincided with Chadwick's

emergence into public life, when giving in 1907 a retrospect of his experience regarding tuberculosis, wrote:

"My retrospect begins in a shaded parlour at Ventnor, a room in which we were taught the art of embalming the air by stuffing cotton about the doors and pasting paper about the window frames. There I had been sent as a little boy for whom it would be very nice to have such a change from the sterner and gloomier climate of a fifteenth century house in the North. . . . So for a time I was to be the child companion of my father's cousin—a pretty lady, sweet and fragile, who had gone to Ventnor for a consumption. . . . Even still I seem to hear the hack-hack of her hollow cough—too hard and hollow to come from that slender body; and again, the quick, stealthy coming and going of the physician; and the mysterious hours in the bedroom—once very long—when I heard whispers of a blood-spitting. Then, when the sun shone—it was winter, and the sun no constant visitor—my delicate lady ventured to pace—how slowly she paced!—up and down the south of the terrace. Such a poor short walk it seemed, after so much waiting and preparation, so much cloaking and muffling, and the eclipse of the hot cheek under the close black respirator, over which the fine Highland woollen veiling was folded again and again. . . .

"At length I went home again, and gladly. The experience was indeed new, and the lady sweet; but it was all weird, still and stuffy, and rather sinister. Happily, I was none the worse; of her or of the respirator I did not even get a scrofula. I was told afterwards that she went with her husband very far away—to Madeira—which I supposed, for her good, to be even stiller and stuffier. But she had died, they said, and we wore black clothes for a few weeks. . . .

"Thus was my little life spared to pry into the affairs of the medical uncles, where I saw more and more of these hothouse plants like my cousin, and wondered whether the gardeners were stupid, or the houses not hot enough—for all of them died! Indeed, no one ever seemed to suppose they would get well! . . .

"Then as a student I began to prowl in the hospitals, where I saw these consumptives in flocks. 'Only phthisis!' was the monotonous diagnosis. They used to sit on a side-bench along with infantile palsies and the rest, not as infectors, but as incurables. Meanwhile they were comforted with large beer-bottlefuls of balsams and liniments—a sort of liturgy, as it seemed to us; for every week one or two came no more, and others took their places."

General Apathy

Yet another witness may be cited as to the limitation of medical thought in relation to tuberculosis fifty years ago. I remember well the disappointment felt by me, on returning to Edinburgh after laboratory work elsewhere on the lines of Koch, by the remark of Sir Thomas Grainger Stewart, one of the kindest of my former teachers. When, in reply to a question regarding future work, I told him I proposed devoting much of my time to the subject of tuberculosis, his remark was: "Don't think of such a thing. Phthisis is worn to a very thin thread. The subject is exhausted." The reply reflected the medical apathy which then prevailed. How curiously in contrast seem the interminable piles of literature devoted to the subject in more recent times!

Again, in 1887, when convinced by laboratory and clinical work that in concerted activity on the part of communities lay the road towards successful handling of the problem, I proposed to civic and medical authorities in Edinburgh that Queen Victoria's jubilee might be fitly commemorated by the inauguration of a movement towards that end, a wet blanket was thrown on the project by the adoption of a city scheme for sending consumptive patients to cottages in the country. It was the apathy of the city fathers and their advisers which led to the establishment of the first tuberculosis dispensary and the development of the Edinburgh scheme on a voluntary basis.

A few years later, when pleading for the establishment of the first sanatorium in Scotland, I was pulled up in fatherly fashion by the learned Principal of the University of Edinburgh for the folly of proposing to treat pulmonary tuberculosis in such a climate.

"When you tell me you have discovered how to get rid of the east wind and Scottish haar, I shall believe you may be trusted to do something to remove consumption, which is the special curse of our climate."

Indications of Changing Outlook

Not many years later one was able to write (1898), as the result of extended observations in the said sanatorium, which—peace to the Principal's ashes!—came into being notwithstanding his good-natured opposition:

"The one essential factor in treatment is the free exposure of the patient to open air. He must be bathed in fresh air day and night, and this irrespective of whether the weather be good or bad, as popularly understood. The more sunshine, or at least bright sunlight, he can have, the better for the patient. . . . Every aspect of climate having been considered, I have been led to the conclusion, which I have now for long taught to the members of my chest clinic, that the best climate for the treatment of pulmonary tuberculosis is that which woos the patient most into the open air. . . . The experience of the past dozen years has convinced me that if the patient can only be persuaded to be out of doors, lying, sitting, or walking, as the case may be, a large part of each day, and, when indoors, to allow the freest access of fresh air day and night, results may be obtained in almost any district which will compare satisfactorily with those obtainable at most favoured resorts."

About the same time, Sir William Broadbent, having visited the sanatorium, in citing the views just expressed, was impelled to write:

"This is not a mere pious aspiration, but a verified experience. [Results] at Edinburgh, on the Norfolk coast, in Ireland, and elsewhere have shown that consumption can be treated successfully in practically all parts of our islands. This has revolutionized our ideas and it has created new duties."

In the same year Sir Samuel Wilks, president of the Royal College of Physicians, wrote from his own experience as follows:

"*The remedy for consumption, therefore, is not medicine but fresh air.* In various parts of the globe this may be obtained. Seeing that all the places best fitted for consumptives are blessed with sunshine, it is quite possible that the latter may be one of the conditions favouring recovery. . . . *Air and sunshine are the needs of the consumptive; without them no other remedies will succeed.* When reading at school of Diogenes in his tub, and the visit of Alexander the Great to him, I thought he was a man of very bad manners in telling the monarch to get out of his sunshine, and it was not until late years that I took a different estimate of the philosopher."

Notification

One other illustration. A day or two after venturing at a public meeting (1890) to urge the desirability of the notification of tuberculosis, I was stopped in the street and reproved by that veteran exponent of notification, Sir Henry Littlejohn, for the foolish notion that a principle applicable to acute infections should be extended to so chronic a condition as consumption. He advised me not to run my head against a stone wall. Yet notification of tuberculosis in all its forms has for some eighteen years been the law of the land. In the year 1929 the cases of tuberculosis notified in England and Wales and in Scotland numbered 86,296. Alongside of notification there has developed throughout the country a uniform system of centres for diagnosis and residential institutions for all the varying manifestations of tuberculous disease. By the adoption of this uniform tuberculosis scheme throughout the kingdom an immense

amount has been effected, notwithstanding the inseparable disadvantages of the years we have lived through since 1914. In spite of imperfections of machinery and inequality of personnel, most convincing results have followed the incessant efforts of understanding officers attached to the tuberculosis service in the country.

MORTALITY FROM TUBERCULOSIS

What are the facts regarding the mortality of tuberculosis at the present time, compared with those past years which we have been considering? They are significant, and deserve to be broadcast repeatedly in view of the ill-informed and foolish statements one hears on many sides. Let me cite a few. If the figures relate to Scotland for the most part, the fact must not be attributed to perfervid patriotism, but rather to the great convenience I have experienced in tapping, on the spot, the resources of the Registrar-General for Scotland, to whom my thanks are gratefully accorded. The returns from England and Scotland are remarkably parallel.

Decline in Mortality

1. During the past fifty years the decline in mortality from tuberculosis has been very remarkable. In Scotland the death rate from all forms of tuberculosis has fallen from 336 per 100,000 in 1879 to 97 in 1928, and the death rate from pulmonary tuberculosis has fallen from 231 per 100,000 to 68. The continuity of the drop is noteworthy.

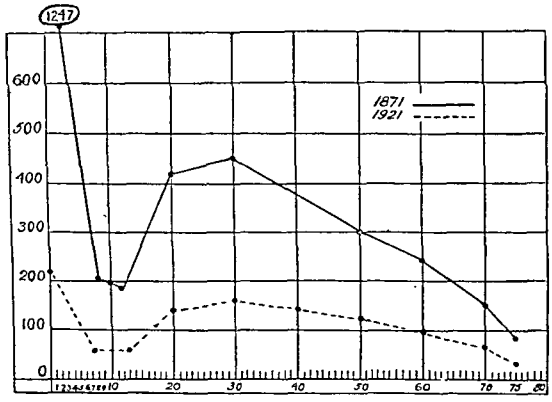

FIG. 1.—Graph showing age death rates for tuberculosis in Scotland.

The graph is of special interest, contrasting as it does the *age* death rates of 1871 and 1921 (last census). While the general form of the curves is similar, the following points are noteworthy: (*a*) the general difference of levels; (*b*) the striking difference at the early age periods; and (*c*) the gradual levelling of the peak in early adult life.

2. The decline in mortality from tuberculosis has been much *more rapid* than the decline in mortality from all causes. Stated broadly, while the mortality from all causes has decreased by approximately one-half, the mortality from tuberculosis and from pulmonary tuberculosis has declined by more than two-thirds. Stated otherwise, while in 1871 the deaths from tuberculosis formed 16.8 per cent. of deaths from all causes, in 1921 they formed only 9 per cent.

Accelerating Decline

3. The rate of decline in mortality from tuberculosis has *accelerated* within recent years. While the percentage decline of rate of mortality from tuberculosis during the decade 1901-11 was 21, the percentage decrease during the decade 1911-21 was 31. This remarkable acceleration of rate is indicated in Table I, where, taking a series of 5-year periods, the mean death rate of each 5-year period is compared with that of the previous 5-year period. The *percentage decrease* in each instance is shown in the last column of the table.

TABLE I.—*Death rate per 100,000 from tuberculosis (all forms) in Scotland, illustrating accelerating fall within recent years; as prepared by the Registrar-General for Scotland.*

Year	Death Rate	Mean Death Rate (5-yearly)	Percentage Decrease since previous 5 year Period
1893	240		
1894	235		
1895	256	239	15.55
1896	229		
1897	237		
1903	216		
1904	224		
1905	211	217	9.21
1906	218		
1907	218		
1913	170		
1914	162		
1915	164	163	24.88
1916	160		
1917	159		
1923	118		
1924	116		
1925	110	109	33.13
1926	99		
1927	100		

The point is illustrated likewise in respect of individual cities—for example, Birmingham, during a period of forty years, 1883-1922. The percentage decrease as between five years (1883-87) and five years (1898-1902) was 4.15, while the percentage decrease as between five years (1903-7) and five years (1918-22) was 24.24.

Unequal Decline in Different Countries

4. The decline in mortality from tuberculosis has been unequal in different countries and different cities, as Tables II and III reveal.

TABLE II.—*Death rate per 100,000 population from tuberculosis: larger cities of Great Britain and Ireland in 1925.*

	Estimated Population	Death Rate per 100,000 from			
		All Tuberculosis	Pulmonary Tuberculosis	Tuberculous Meningitis	Abdominal and other Tuberculosis
London ...	4,612,000	112	95	8	10
Glasgow ...	1,033,999	137	97	14	25
Birmingham .	945,900	114	95	8	11
Liverpool ...	856,000	151	121	11	19
Manchester ...	755,800	158	133	9	16
Sheffield ...	527,100	99	79	9	11
Leeds	472,900	129	107	9	14
Edinburgh ...	421,968	134	95	14	26
Bristol	386,000	120	95	9	16
Bradford ...	290,200	101	81	8	12
Newcastle-on-Tyne	287,100	156	121	16	19
Dundee ...	169,361	122	87	11	24
Aberdeen ...	157,192	124	97	11	16
Belfast County Borough	413,000	187	138	20	29
Dublin Area...	438,000	186	144	42	

TABLE III.—*Death rate per 100,000 population from tuberculosis in American and European cities (outside Great Britain) during 1920.*

American Cities	Estimated Population	All Tuberculosis	European Cities	Estimated Population	All Tuberculosis
Philadelphia..	1,837,924	137	Vienna ...	1,842,005	405
Indianapolis ..	314,194	132	Budapest ...	—	376
Newark ..	414,216	130	Warsaw ...	—	338
San Francisco	520,546	128	Prague ..	487,000	324
Boston	751,251	127	Florence ...	248,587	293
New York ...	5,663,980	126	Paris	2,905,218	279
Pittsburgh ..	591,033	119	Köln	656,617	189
Cleveland ..	808,253	108	Leipzig ...	621,351	179
Buffalo... ..	519,503	102	Berlin ...	1,931,339	177
Chicago ...	2,728,022	97	Düsseldorf...	414,900	172
St. Paul ...	290,000	89	Amsterdam	650,758	156
Washington ...	437,571	85	Hamburg ...	1,011,000	152

The discrepancies between cities in Great Britain and Ireland are most noteworthy. Similar discrepancies are found in the towns of the United States, and become still more arresting when we review cities in other European countries. Note the inequality among cities in our own country. For example, in 1925, the death rate from tuberculosis per 100,000 of the population was in Sheffield 99, London 112, Manchester 158, Belfast 187. In cities outside Great Britain the inequality was even more striking. Comparable statistics for the year 1920 indicated that the death rate from tuberculosis per 100,000 of the population was in Washington, D.C., 85, Chicago 97, New York 126, Philadelphia 137, Berlin 177, Paris 279, Warsaw 338, Vienna 405. The comparison throws doubt on the explanation frequently cited on the authority of Metchnikoff that diminution in mortality from tuberculosis is the expression of an advancing immunization of civilized populations against the disease.

While the significance of progressive immunization in certain directions is admitted, the examples just cited indicate that tuberculosis continues to be unequally distributed throughout the civilized world, and that the distribution does not appear to bear close relationship to the influence of immunization. Were progressive immunization the chief factor, we might rightly expect to find evidence of the influence conspicuous among the populations of the older civilizations. The figures in the above tables cannot be said to bear that out.

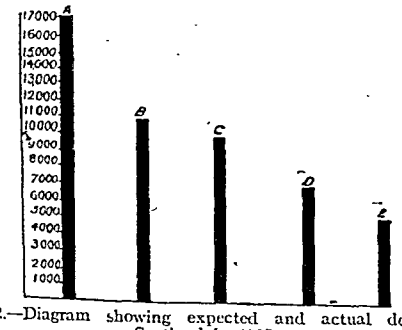

FIG. 2.—Diagram showing expected and actual deaths in Scotland in 1925.
(Note.—All numbers are based on five-yearly returns.)

Without attempting to analyse all the factors, we may conclude generally that in some countries and some cities causes making for tuberculous disease remain prevalent, and that influences making for diminution have, for one reason or another, had less effective play.

Returning to the facts of our own country, the main propositions regarding the decline and acceleration of the decline are strikingly illustrated in the accompanying diagram (Fig. 2).

The columns indicate that the number of deaths that might have been expected in Scotland in the year 1925, (A) if the death rate had remained the same as in 1875; (B) if the death rate of 1900 had continued; (C) if the tuberculosis death rate had declined during the whole period in the same ratio as the death rate from all causes; and (D) if the death rate during the second half of the period had declined in the same ratio as during the first half of the period—that is to say, if there had been no acceleration of decline. The last column (E) shows the actual number of deaths.

Results Follow Intelligent Action

Such facts are inspiring. From whatever angle the evidence is considered, it seems fair to conclude that the decline in mortality has been hastened by the fuller understanding of the natural history of tuberculosis, which has been rendered possible by the discovery of the tubercle bacillus and by the more correct outlook on the field and the better adaptation of measures of attack and defence.

A comparison of the epidemiological records of different countries points to the conclusion that by the adoption of a certain procedure it is possible to influence the morbidity of, and the mortality from, tuberculosis. In other words, the tuberculosis index of a given area is dependent on, and governable by, the degree of intelligent action on the part of health authorities and of co-operation on the part of the inhabitants. The scoffer who tells us that the decline in mortality so evident in Great Britain to-day is referable to causes acting uniformly throughout the world does not know, or is unwilling to face, the facts.

In view of the evidence, it is clearly up to every progressive community to understand the *why* and the *how* of each factor in the tuberculosis scheme of the country, and to insist on its adequate application.

Have we Reached Finality?

If we assume that this is realized, the question arises: Have we then reached finality? May we rest content with the results attained and the accelerating rate of decline in tuberculosis mortality presently apparent, in the belief that we are within sight of the date when the descending curve of mortality will reach the vanishing point? Shall we be content to wait and see?

To such a question the answer can be only an emphatic negative. With the constantly increasing knowledge of the natural history of the disease there is a recurrent call for fresh orientation. Action under the tuberculosis scheme is not stereotyped, but can be adjusted to meet the indications afforded by every new fact and fresh conception based thereon. Unfortunately the influence of habit and tradition tends still to dominate the situation. Even now the bearing of some well-ascertained facts remains inadequately realized in the preventive programme.

The chief weakness of the present-day attitude is the disproportionate concentration of attention on pronounced lesions, more especially pulmonary tuberculosis. This is a natural result of the earlier outlook and of the gravity of the condition itself. Fifty years ago little attention was paid to anything save advanced disease of the lung. And it is most fitting, from the individual and communal point of view, that tuberculosis of the lung should have special consideration. The advance made during the past forty years in connexion with the diagnosis and treatment of pulmonary tuberculosis ranks as one of the most encouraging facts in the history of practical medicine. On the other hand, it should be kept well in mind that, for the most part, pulmonary tuberculosis—"phthisis" as, unfortunately, it is still sometimes termed—is in reality

a late visceral manifestation of an infection contracted much earlier.

From the larger preventive point of view it is necessary to probe more deeply. Attention must be shifted more and more towards the earliest *indications of tuberculous infection*—not to the neglect of late manifestations, but to their better interpretation and progressive elimination.

CHANGING ORIENTATION

Continued observation of the natural history of the infection, the lessons of experiment, and the facts of comparative pathology—for example, tuberculosis as it occurs in cattle—together with the introduction of tuberculin tests, have made possible a truer perspective.

The gradual dissemination of tuberculous infection and the resultant disturbance have been followed from the point of infection through the lymphatic system to involvement of the various viscera. The march of events may be readily studied in animals, when inoculated either naturally or artificially. In the human subject, it is one of the privileges of age to have had the opportunity time after time of watching the procession of events in the same individual *from the date of initial infection and trifling manifestations, through the varying phases of the infected individual's life.* It has been possible for me in numerous instances to trace the development of tuberculosis in the same subject in ever-changing form, from the seed stage up to full fruition, in some instances for thirty years and more.

BIOLOGICAL METHOD

How slight and apparently simple the first indications may be! How gradually those may become pronounced and fixed—it may be in glands—receding here and advancing there! And the same ebb and flow may be observed in visceral involvements—periods of activity alternating with quiescence. The latency may be so complete as to simulate arrest. Yet this in turn may be followed by a fresh outburst.

The march of events throughout the long or short life of the infected individual, passing panorama-wise before the observer, is a fascinating study. That ebb and flow—that arrest and advance, occurring irregularly throughout many years—are but the expression of the continuing contest between the invading organism and the resistance of the tissues of its host.

The variety of expression is infinite. While the invading organism is presumably little changed, save in respect of numbers, the resistance offered varies endlessly in different individuals and in the same individual at different times. This results from many causes—intercurrent illness, accident, strain (at different stages of life), and a host of environmental influences.

The tuberculosis scheme, as usually developed, tends to be lopsided, heavily weighted in respect of pronounced lesions and but little occupied with the possibilities and consequences of early infection. In the absence of so-called clinical disease, too little attention is paid to the fact that tuberculous infection has been established. And yet this is the crossing of the frontier—the beginning of what is often a lifelong contest.

CARDINAL FACTS

In its everyday operations the tuberculosis scheme frequently lacks grip on certain facts of primary importance.

1. That infection is widespread, indeed more or less universal, throughout a community.

2. That infection is contracted for the most part in childhood.

3. That tuberculous infection, once established, continues to exert its influence throughout the life of the individual, either by securing protection—immunity—from the consequences of further exposure, as happily occurs in the majority of individuals, or by producing recurrent disturbances which are precipitated by many different causes—personal and environmental—and which vary endlessly in kind and in degree.

4. That in proportion as the resistance of the infected individual is kept high, these disturbances are likely to be few and relatively slight. In proportion as the resistance is lowered by any cause, the infection is apt to spread, and existing lesions tend to be activated and extended.

To no other disease is the classical maxim so applicable: *Venienti occurrite morbo.* Anticipation, that is, prevention, of the endless possibilities of subsequent mischief following infection was the *motif* behind my insistence on the systematic examination of contacts as an essential function of the tuberculosis dispensary. If our efforts towards the eradication of tuberculosis from a community are to be effective, it is necessary that we should hunt for the earliest traces of tuberculous *infection.* The advanced case of disease is but the late efflorescence of the full-grown weed, which might have been scotched at the seedling stage. To neglect the methods of early detection with a view to arrest is medically and economically unsound.

FUNDAMENTAL VALUE OF TUBERCULIN

Having regard to the likelihood of infection in the course of childhood, and the difficulty of assessing the ultimate consequences of such infection, I am firmly convinced that the general use of tuberculin as a diagnostic agent in childhood is most desirable. Because of the likelihood of infection, the tuberculin test should become routine practice at stated intervals from early infancy onwards. The procedure is painless and harmless; yet the knowledge obtained by it is priceless.

So long as the reaction remains negative, nothing further is necessary. Whenever a positive reaction is obtained for the first time, the fact and the date should be recorded. The fact of tuberculization, and the date of its first detection, are of immense significance in the life-history of the child, having regard to the possible implications.

If, after positive determination, the health of the child continues thoroughly good, we have the knowledge that the child's resistance is sufficient, and there is no call for treatment. On the other hand, the positive determination may illuminate many after-events. Vague conditions of "delicacy" in the child may find their explanation—for example, malnutrition, obscure feverish attacks, ill-defined lack of energy, so-called "disturbed action of the heart," which may interfere with the claims of education and sport. Such conditions, I am satisfied, are very frequently the expression of tuberculous infection. Further, the occurrence of incidental illnesses, such as measles and whooping-cough, will call for watchfulness, and care will be taken to secure complete convalescence after such attacks. The doctor will insist on the maintenance of a high level of resistance, more particularly in relation to school life, the period of adolescence, and the time of entrance into more responsible life.

Preventive medicine may wisely take a lesson from the sphere of agriculture. The practical farmer who seeks to raise a tubercle-free herd has learned the value of the tuberculin test. A method for the early detection of tubercle which is worth the farmer's while on economic grounds has still greater significance and wider efficacy—both medically and economically—in dealing with the human race.

Through the knowledge gained by the tuberculin test, the intelligent farmer is able to direct separate attention

to two groups in his herd: (*a*) to those animals which react to tuberculin, and (*b*) to those which do not react. If his purpose is solely to secure and maintain a tubercle-free herd, naturally he removes the reactors entirely. On the other hand, he may prefer to retain the reactors, as a group by themselves, in which case he will take special precautions for their individual care and their communal relationships.

These things are a parable. In view of the frequency of infection in the human family, I am satisfied that, while insisting on the undesirability of any formal distinction between reactors and non-reactors, it would constitute an advance of first importance could it be made routine practice to determine the *fact* and *date* of the initial infection (tuberculization) in every child. This important subject has been elaborated by me elsewhere.

Such determination is the first essential step towards effective detuberculization of the individual and, ultimately, of the community. The procedure is harmless and costs little. Yet its general adoption would result in the anticipation and limitation of countless consequences in the shape of invalidism and crippling. It is the lack of such scientific anticipation which has created, and meantime maintains, the need for sanatoriums and hospitals all over the country. As I put it in 1912: "It is to the nursery and schoolroom that observation and effort should be directed if measures for the eradication of tuberculosis are to be fundamentally sound and practically effective."

ADMINISTRATIVE DEFECTS

It is one of the disadvantages of our public health system that divisions made for administrative convenience do not always coincide with the grouping of individuals from the standpoint of the physician. The departmental system which has developed in relation to the public health service leads sometimes to embarrassment and incomplete results.

Especially is this true of the line of separation between the department of maternity and child welfare and that of tuberculosis. In actual practice that artificial barrier should cease to exist. The liaison between these two departments ought to be of the closest kind. Falling administratively within the province of the maternity department is to be found the tuberculous mother—expectant, or after the event—with the variety of difficult problems which her presence brings. Then there is the problem of the newborn child and of other infants from tuberculous mothers. There is also the question: How are infants generally to be safeguarded from the ubiquitous infection?

The department of child welfare, as such, is of limited value unless the likelihood of tuberculization during the early years of life is kept steadily in mind and the advent of *infection*—as opposed to the appearance of definite *disease*—watched for with scrupulous attention. It should be regarded as a responsible duty of the department—as it should be of the family doctor—to instruct the ordinary mother regarding the likelihood of the occurrence, the ready means for determining this, and the simple measures to be taken to avoid serious consequences.

ANTICIPATORY MEASURES: VACCINES

With the knowledge we now have of the genesis and distribution of tuberculous disease, it is high time that the medical adviser of the household, whether the family doctor or the health officer (to whichever department he is attached), should see that the parent or responsible guardian understands the available methods for excluding the risks of tuberculous disease. The meaning and value of anticipatory (preventive) procedure should be inculcated on parents from the birth of the child onwards, and procedure on the lines indicated should be commenced at an early date. I have the conviction that extended knowledge of the facts, and the application of anticipatory measures which will be consequently demanded, will lead to better results than attempts along the line of enforced vaccination.

Attempts at vaccination have been numerous. It is foreign to the purpose of this address to refer to those in detail. One after another they have been proposed on scientific grounds. In some cases they have been boomed less desirably. They have been tested and, so far, all have been found wanting. The latest proposal is at present valiantly championed. The vaccine B.C.G. awaits the final verdict, but I think it only right to say that in my opinion there remain loopholes in the evidence which call for further examination before it would be proper to sanction the adoption of the B.C.G. method generally. Owing to the continuing lack of certainty on several issues, and the difficulty of determining the limits, on the one hand, of the risk, and on the other hand, of the protection following B.C.G. vaccination, it has seemed to me remarkable that what may be described as an experiment on the human subject should have been permitted on so large a scale.

Looking to all sides of the question in the light of present knowledge, I am convinced that the proper line meantime is to concentrate attention on the detection at the first possible moment of the occurrence of tuberculous infection (tuberculization) in the child. This event, which can be determined exactly by means of the tuberculin test, gives the key to much that may be otherwise obscure in the life-history of the individual, and opens the way to the rational and timely employment of preventive and curative measures. Were this line of approach adopted universally, I am satisfied that the after-consequences of the infection would be correspondingly reduced and that not only would the decline of mortality from tuberculosis be further accelerated but that—assuming thoroughness of procedure—we might expect to reduce the mortality from tuberculosis to a negligible amount within a generation or so.

Neither child nor calf is born tuberculous—even if born of a tuberculous mother. Exception to the rule is a very rare occurrence. Tuberculosis was unknown to the wild man of the prairie, the forest, and the hills. Like cattle, living and breeding in the open, he was exempt. The blight of tuberculosis has followed incessantly the aggregation of men in groups—one of the vicious by-products of incomplete and ill-informed civilization. Begotten among these conditions, and fostered by ignorance and dread, it has shadowed man from the cradle to the grave. Tradition and fear have engendered hopelessness and helplessness. Mankind, stricken and crippled—mankind in all its ranks, for tuberculosis knows no class distinction—was in a sorry way. Medicine, blindfold, stumbled in the dark.

The past half-century has changed all this. There is light at every point on a sure road. What we require now is wide extension of the lighting system. Better training of our doctors will bring precision of effort towards the prevention or limitation of tuberculosis. Popular education regarding the causation and natural history of tuberculosis will arouse the health conscience of the community to demand that nothing be left undone to ensure that this "great disease of life" shall cease.

It has been given to few to realize so clearly as did Sir Malcolm Morris how true it is that the final conquest of tuberculosis depends on the provision of better lenses for the doctor and more active insistence on the part of the people. He looked confidently for the dawn of "that great to-morrow when mankind shall mend."

A PLEA FOR THE EARLIER DIAGNOSIS OF ABDOMINAL EMERGENCIES*

BY

C. H. FAGGE, M.S., F.R.C.S.

SURGEON TO GUY'S HOSPITAL

In the treatment of an acute abdominal emergency which has passed beyond a certain stage in a patient whose condition is such that the natural powers of recovery have been put out of action by toxins elaborated within the paralysed bowel, we are, broadly speaking, as powerless as were those who were faced with the same problem forty years ago. It is true that prognosis in a majority of the conditions which are generally recognized as abdominal emergencies has much improved, but it is my thesis that this is due to earlier diagnosis—to the recognition of a morbid process in a stage which was not in those days regarded as a pathological state requiring surgical treatment, and not to any new epoch-making measures, either of manipulation or of therapy. That there is still room for improvement in prompt diagnosis must be admitted, even though some of us have had the fortunate experience to see cases of advanced peritonitis recover, and have perhaps attributed this to the use of the Fowler position, morphine, and rectal saline; and probably many will agree with me that the use of anti-gas-gangrene serum for such a patient, or for one suffering from acute obstruction of some days' duration, is of the greatest value at times.

This line of treatment, which we owe to one of the best pieces of surgical research of recent years, is entirely British, having been evolved by Williams of the Surgical Unit of St. Thomas's Hospital. In spite of some degree of success in conditions just spoken of, we must in our inmost hearts admit that the large number and the diversity of aim of the measures recommended for lesions such as paralytic ileus conclusively prove that we have no sure remedy for it, and must own that resections of gangrenous gut still show so high a mortality as to make any surgeon thoroughly dissatisfied with present-day methods.

For progress a contented mind is a drug of evil influence; the first step in the discovery of a new line of treatment is the appreciation that methods hitherto employed have not produced results which may be regarded with complacency. It is clear that the calls on our time debar, and that opportunities are lacking for most of us to embark on, research, quite apart from the fact that the research spirit, the critical mind, is given to very few, and, for this latter reason only, much that passes as research has very little practical value in our warfare against disease. But if this method is not at our disposal, we have abundant opportunities for clinical observation, and I submit it is by the use of this and a finer perception of the meanings of signs and symptoms of morbid conditions, that we shall be enabled to arrive at an earlier diagnosis of abdominal emergencies which up to the present have proved so obstinate to operative treatment. By this means the present heavy mortality will be appreciably diminished.

Visceral Pain

The first, and most important and also most informative, of the signs and symptoms which suggest an acute abdominal emergency is pain. Any severe abdominal pain lasting for a period which is expressed in terms of hours rather than minutes, and for which a definite and adequate cause cannot be found and demonstrated, should, in my judgement, be regarded as probably due to a surgical emergency, and the patient placed at once under such conditions that, when confirmatory evidence is forthcoming, operation may be undertaken without further delay.

In my Bradshaw Lecture (given in November, 1928) I made an attempt to formulate a mechanical theory for the production of the various axial rotations which take place in the abdomen. Many of these are pathological, and when investigating the subject I could not but come to the conclusion that such rotation of a mild degree must often take place without causing any grave result, in fact that a preliminary minor degree of torsion usually occurs several times before the process goes so far as to interfere with the vitality of the organ concerned. Such a minor rotation, which it is assumed may be corrected by a reversing of the same factors which caused it, must undoubtedly produce pain as its first symptom; this may be of short duration—for example, a few minutes. One naturally speculates as to whether some transitory severe pains may be of this nature. Many theories have been put forth to explain the nature of abdominal pain. This is of two types: local and referred. At present Hurst's† hypothesis that visceral pain is due to tension has more in its favour than any other theory. It is clear, too, that pain is only a superlative degree of the sense of fullness or discomfort which follows for a brief time the temporary distension, perhaps scarcely more than physiological, of any hollow organ such as the stomach. Pain is a manifestation of the degree and rapidity of production of visceral tension, and while it is produced only when there is increased motor activity, we are told by writers on the subject that it cannot be regarded as an exaggerated form of colic, which is attributed by Meltzer (1903) to a disturbance of the normal relaxation of the bowel below, which usually accompanies the contraction of the intestine when stimulated at any spot. To me it appears that the difference is only one of degree. Further, if we accept this association of visceral pain with increased motor activity we can understand why various forms of intestinal ulceration are usually painless. The conclusion that true visceral pain exists is inevitable, in spite of the contention of Lennander and others that the viscera are insensitive to mechanical stimuli, and that therefore pain must be a manifestation of inflammation or of traction on the parietal peritoneum and extraperitoneal connective tissue.

Referred Pain

In addition to local visceral pain as a manifestation of disease, we recognize the phenomenon of referred pain. Ross termed visceral pain "splanchnic," and referred pain "somatic"; the latter, first described by John Hilton as "sympathetic pain," is now generally explained as being referred to a cutaneous area which is innervated by the same spinal segment as the viscus affected. The intensity of such pain varies with many factors, and unfortunately we can never lose sight of the fact that "the threshold of stimulation" may be lowered by many conditions, not necessarily functional, so that the estimation of such pain is by no means a correct index of the severity of the patient's condition. Visceral pain is located to the position of the organ concerned—for example, pain resulting from an inflamed gall-bladder may vary in position with that of the gall-bladder itself. This is denied by Hurst. It is true, as we shall see later, that there are exceptions to this plan, but when we are told of pain over a certain organ we usually conclude that disease of the subjacent organ is the cause of the pain, and in general this is correct. Associated with visceral pain is deep tenderness; this is found over the same area as the pain: possibly of the same causation as referred pain are hyperaesthesia (or superficial tenderness) and rigidity. The two latter are presumably manifestations of spread to the somatic fibres of the spinal segment involved with lowered resistance to such stimuli, and naturally are found affecting the two

* Substance of a paper read before the Croydon Division of the British Medical Association.

† Goulstonian Lectures on the Sensibility of the Alimentary Canal, London, 1911.

layers of the abdominal wall sensitive to pain: (1) the skin, and (2) the muscle layers.

I have purposely discussed the phenomenon of pain at some length because I feel that unless we have some knowledge of the method of its production and of its significance we can form no reliable estimate of its diagnostic worth.

Vomiting: Shock

Vomiting is usually an early sequel of acute abdominal pain: it follows so shortly the first symptoms that it cannot be due either to the spread of inflammation to the visceral peritoneum or to mechanical causes such as ileus. Its origin must be reflex, and it can probably be explained as a reflex excitation of the motor segments controlling the stomach. In nature this vomit is merely gastric contents, is often small in amount unless medicine has just been taken, and cannot be expected to occur more than once or twice.

As a general rule symptoms and signs of shock are absent at this stage of an abdominal emergency (apart from internal haemorrhage—for example, ruptured ectopic gestation). I would not go so far as to accept Moynihan's view that in the early hours of an acute abdominal emergency shock does not occur, but would remind you that it is usually absent; in fact, every one of us must have seen such a severe condition disclosed at an early abdominal operation as to evoke the spontaneous remark, "Why was there no shock?" To this I have always given the second-best answer to any question, "I do not know."

Distension: Visible Peristalsis

Distension cannot be expected at the stage in which a diagnosis should be made—and I wish particularly to emphasize this point because textbooks, in an endeavour to omit nothing which may possibly occur, tend to convey erroneous ideas and an inaccurate clinical picture. When distension is present in an acute case, usually after forty-eight hours, and never in the first twenty-four, it is commonly due to paralytic small gut obstruction (ileus) and indicates peritonitis. Far less frequently it may be seen in acute small intestine obstruction, but again only at a stage when the diagnosis has or should have been made on other evidence.

Visible peristalsis indicates hypertrophy of the muscular coats, and therefore occurs only in chronic obstruction: we should not be misled by seeing the normal peristalsis of bowel through a thinned abdominal wall.

Indications for Operation

What is the evidence?—a patient with a few hours' acute abdominal pain followed by vomiting; but if confirmatory proof is still considered wanting the patient is kept in bed and a half-hourly pulse chart ordered. This practice is not universal, as it should be, for, apart from the pain, the most valuable sign is a rising pulse. If after two to three hours the pulse is rising, the abdomen *must* be opened at once. A rise within half an hour of admission may be ignored, as this is often accounted for by such washing as is necessary, the giving of a plain soap enema, or purifying the abdomen; the last is not done, nor is morphine given, in wards under my control, until a provisional diagnosis has been made. I have so far been intentionally vague, and have purposely mentioned no sign or symptom which would concentrate attention on any particular organ. Shall we say that one-third of abdominal emergencies are obvious, one-third doubtful, and one-third impossible of diagnosis? If we are going to save the impossibles certainly, and a fair percentage of the doubtfuls, operation, assuming that it is necessary, must be done in this stage before vomiting has become frequent, before there is any distension, before abdominal movements have ceased, or the abdominal facies indicates unhesitatingly the patient's grave state. All these signs mean peritonitis, which in most cases is preventable.

In urging immediate exploration under such circumstances I would state at once that I do not regard acute cholecystitis as an emergency; as a rule the pulse, if it has risen before admission, falls when rest is assured, but if in doubt I would prefer to operate on a mistaken diagnosis, being glad to find only a swollen thick adherent gall-bladder, when perhaps an acute gangrenous appendix was expected. Abdominal examination on the patient's admission may disclose the scar of a previous laparotomy, and the presence of this with a history of acute pain would compel me in every case to investigate at once; for acute obstruction due to kinks, angulations, etc., can be easily relieved, provided the bowel above the obstruction has not become paralysed beyond hope of recovery. In the more serious condition, where a band or other structure threatens the vitality of an intestinal loop, we must realize that once circulation in the veins has ceased, recovery of the intestine is impossible; thus resection with all its horrible sequels and its extremely grave prognosis is inevitable.

In spite of the fact that in a sense it weakens my present thesis, I feel bound to admit the relative rarity of acute small intestine obstruction as compared with acute inflammatory conditions which spread to the peritoneum and so induce ileus or small gut paralysis. As a result of this the bowels cease acting and enemata produce no effect, so that an erroneous diagnosis is often made of acute intestinal obstruction when the condition is really one of peritonitis, following acute appendicitis, diverticulitis, etc.; the converse mistake is, in my experience, never made. Of all abdominal emergencies at least 50 per cent. result from acute appendicitis. It has always been my habit, when summoned by my house-surgeon to an emergency, to endeavour at once to disprove his diagnosis; but he who persistently diagnoses acute appendicitis is rarely wrong, and when he is, it is probably better for the patient, and certainly better for the house-surgeon's mental training, to have made the mistake than to have been right.

Beyond the evidence that has already been referred to, I place in the diagnosis of acute appendicitis the greatest reliance upon localized rigidity; when present, this involves the right lower rectus and obliques, and may be absent when the appendix lies in the pelvis. It is also absent or much diminished for the first few hours after the appendix has perforated, but as a rule is present before the initial abdominal pain has migrated to the right iliac fossa, which it usually does in from six to twelve hours after its onet. Even although in acute salpingitis there may be much more pain on one side or the left side alone may be affected, there are in this condition a rigidity of the lower abdomen on both sides and often a similarly placed sense of fullness, and the patient as a rule has no aspect of severe illness. Much can be learnt from a description of the pain—its constancy, its severity, and, if it ceases, the manner of its passing off. The pain of acute obstruction is variable—spasmodic—as is that of colic. No pain equals in severity that of perforation of a hollow viscus. The pain due to colic subsides quickly and is suddenly gone, quite unlike that of acute inflammation—for example, appendicitis.

Finally, if these evidences are accepted which lead, as I have said, in one-third of acute abdominal emergencies to a correct diagnosis, and in perhaps another third to an inkling of the morbid condition present, there still remains one-third in which, I submit, only by prompt intervention can a favourable result be assured. If the doubtful cases are included—and many of them must be—my plea becomes of greater import.

REMOVAL OF PORTIONS OF MALIGNANT TUMOURS OF THE RECTUM FOR CONFIRMATORY SECTION

BY

W. B. GABRIEL, M.S., F.R.C.S.

SENIOR ASSISTANT SURGEON TO ST. MARK'S HOSPITAL, LONDON

The removal of portions of malignant tumours for confirmatory section is often desirable, but fraught with danger in many situations. It may be dangerous for anatomical reasons, as in the case of the pancreas, or owing to difficulty of access, or there may be danger of spreading the disease into healthy tissues—for instance, an incision into a cancer of the breast or a sarcoma of bone to obtain tissue for section is generally condemned. The rectum and lower pelvic colon, however, present a very favourable part of the body for this purpose: it can be easily reached by a sigmoidoscope without pain or the use of an anaesthetic, and malignant tumours here grow in such a way that portions may be removed from the lumen of the bowel without danger of perforation or serious haemorrhage. The danger of disseminating the disease by removing a small piece of tissue from the surface of the growth must be almost negligible—very little greater than the danger involved in the passage of faeces over the growth.

INDICATIONS

The indications for this procedure in my opinion are as follows.

1. In operable tumours for which radical operation is proposed, if a piece is taken for section when the patient is first seen, the report should be available in a few days, before any extensive surgical operation is undertaken. This confirmation of the clinical diagnosis is welcome, and the rare errors in diagnosis may be disclosed. Occasionally, if a very highly malignant form of growth, such as a colloid carcinoma, is clearly revealed, the intention of performing a radical operation may reasonably be abandoned, since it is the almost universal experience that in this type of growth the results of radical operation are so bad as to render the hope of cure quite remote.

2. In all cases of carcinoma of the rectum for which radium treatment is proposed representative pieces of the growth should be taken for section. From a scientific point of view the necessity of establishing the diagnosis of malignancy by a section is evident: from a practical point of view there is the possibility that the histology of the growth may be of great assistance in deciding whether radium treatment should be undertaken or not. From a study of cases graded by Broders's index of malignancy, Rankin[1] considers that the highly malignant Grades 3 and 4 often react favourably to radium treatment, but constitute a class with a very bad prognosis after radical excision. He recommends removal of a piece of tissue by means of a cautery knife, with a view to grading the carcinoma before deciding on treatment. This method of attempting to assess the malignancy of rectal tumours is one which may prove of great value, although very often ulceration and infection of the growth at the point where tissue is removed may render the histological appearances difficult to estimate.

3. In ulcers of a doubtful nature a portion of the growing edge removed in this way may clear up the diagnosis.

4. In inoperable cases of cancer of the rectum the diagnosis of malignancy should, if possible, be confirmed by section Patients sometimes survive for unexpectedly long periods with palliative treatment alone, or after colostomy has been performed, occasionally living so long that the accuracy of the original diagnosis may be doubted. The following case may be quoted.

CASE REPORT

A woman, aged 47, attended the out-patient department of St. Mark's Hospital in October, 1920, complaining of pain in the lower abdomen and rectum, diarrhoea, discharge, and difficulty in getting her bowels to open. She was examined by my colleague, Mr. Norbury, who found an extensive growth in the rectum, with considerable fixation posteriorly: the clinical diagnosis was carcinoma of the rectum. She was admitted into the wards soon afterwards, under the care of Sir Charles Gordon-Watson, who confirmed these findings.

On October 28th, 1920, he opened the abdomen through a left rectus incision: the growth was felt from above and was found to be fixed posteriorly: there were palpably enlarged glands, but the liver was apparently free from secondary deposits. A left rectus colostomy was established. On November 8th, 3 c.cm. of cuprase were injected intramuscularly; followed a few days later by collosol selenium—5 c.cm. intravenously. These injections were repeated alternately at intervals of a few days, and on her discharge to the out-patient department Mr. Norbury continued them intramuscularly at intervals of a week at first, gradually extending to three weeks.

The improvement in the patient's general condition appears to have been progressive. A year after operation she was recorded as being very well and putting on weight. In February, 1923, Mr. Norbury described the case before the Subsection of Proctology of the Royal Society of Medicine.[2] The patient's general health was then excellent. She had had practically no discharge from the rectum for two years: no growth or ulceration could be seen or felt in the rectum. There was much narrowing of the pelvic colon just beyond the recto-sigmoidal junction. Nothing abnormal could be felt per vaginam.

She was kept under observation, and in July, 1924, a hard swelling was noted in the posterior rectal wall. The injections of cuprase were begun again, and in October, 1925—when I took her over—she had received the large total of 156 c.cm. of copper preparations (cuprase and Crookes's collosol cuprum) and 140 c.cm. of collosol selenium. She was then in very good health; there was no sign of any active growth in the rectum, and all that remained of the former mass was some induration posteriorly, possibly extrarectal. She remained under my observation, and finally, in October, 1928, a barium enema was found to pass freely from the lower colostomy opening to the anus, so I recommended her for readmission for closure of the colostomy. This was done by Mr. Milligan. She was discharged on April 2nd, 1929, and remains in good health, ten years after first coming under operation.

The history is a long one, and the result is very remarkable. Unfortunately, however, there is no microscopical diagnosis of the original condition. Clinically, there is no doubt whatever that the condition was a carcinoma, the splendid result being obtained by the colostomy and by Mr. Norbury's intensive treatment with cuprase and selenium. The sceptic, however, may consider that the condition was a granuloma, which time, aided by the colostomy, has healed. A piece of the tumour taken for section in the early days would have enabled a complete and incontrovertible report of the case to be published.

METHOD.

The instrument recommended is Brüning's forceps fitted with hollowed cutting ends 0.5 cm. in diameter. The example illustrated (Figs. 1 and 2) was obtained from D. Simal, 26, Rue des Écoles, Paris, and can be recommended as a very efficient and smooth-working pattern. The shaft is adjustable in size and is fixed in practice at such a length that the working end will project about two inches through the selected sigmoidoscope. Care must be taken that the milled screw governing the wire cable is tight, otherwise, when dealing with a scirrhous type of growth, the jaws may be found not to close with sufficient strength to be effective. I have

recently had a slightly larger cutting end made with a diameter of 0.8 cm., which I consider to be an improvement, since it enables larger pieces of growth to be removed.

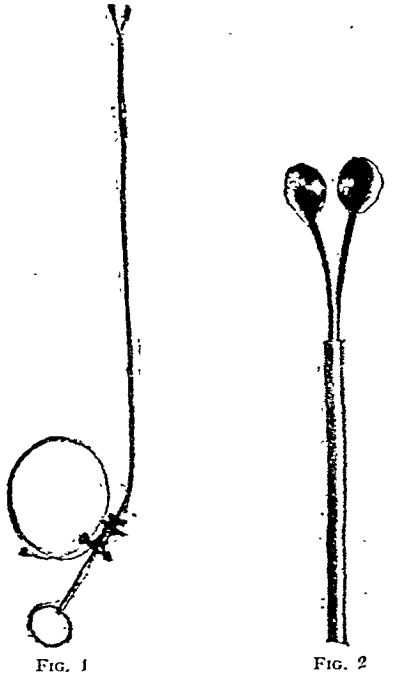

FIG. 1 FIG. 2

FIG. 1.—Photograph of Brüning's forceps.
FIG. 2.—A near view of the working end of the instrument.

When a clear view of the growth has been obtained through a sigmoidoscope, the Brüning's forceps is passed down, and representative portions of the surface or edge of the tumour are nibbled off. I have obtained good specimens from tumours at varying distances from the anus,

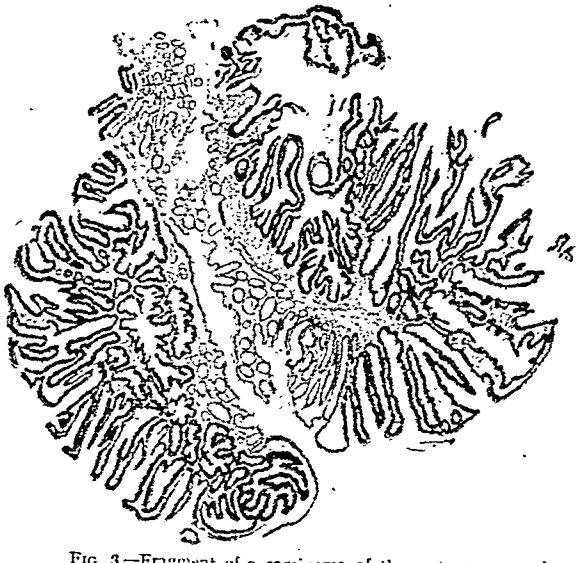

FIG. 3.—Fragment of a carcinoma of the rectum removed with Brüning's forceps: distance 20 cm. from the anus. Laparotomy revealed an inoperable growth with extension to a loop of adherent small intestine.

the highest being at 24 cm. There is no difficulty in taking portions from these distant tumours, apart from the occasional one of passing a sigmoidoscope to these lengths. The pieces of growth come away uncrushed, and are transferred at once with a needle to the formalin-fixing solution. It is generally advisable to remove three to six pieces, which can later be embedded together, cut, and mounted. Thus on each slide several sections of the tumour will be available for study. The sections are compact and generally give an extremely good idea of the histology of the growth.

RESULTS

By means of this forceps forty cases, diagnosed clinically as carcinoma of the rectum, have been investigated. The tissue removed at the first trial has been sufficient to establish the microscopical diagnosis of malignancy in

FIG. 4.—Fragment of a carcinoma of the rectum at 10 cm. from the anus. Diagnosis confirmed later after perineal excision.

thirty-nine cases. Figures 3, 4, and 5 show representative sections of this series as seen through the low power of the microscope. Only one case caused some difficulty: this was that of a young girl, aged 15, who had a massive growth of a scirrhous type filling the pelvis and obstructing the rectum. At the first attempt to remove tissue for section I found the growth so hard that only small pieces of tissue could be removed, and these on section were found to be normal mucous membrane. At a second trial I passed a smaller sigmoidoscope to a higher level and

FIG. 5.—Fragment of a carcinoma of the rectum 15 cm. from the anus. Diagnosis confirmed after perineal excision.

succeeded in obtaining some larger pieces of growth, which clearly proved the condition to be a columnar-celled carcinoma. Thus the diagnosis of malignancy has been established microscopically for the entire series of forty cases.

Spastic Paralysis

In these cases the slinging method, by removing some extraneous sources from which stimuli productive of spasm may be derived, allows a development of power and movement in the over-stretched opponents of the contracted muscles; it reduces the tension in the latter (contracted) muscular group to a minimum; in this particular connexion, perhaps the most important of all, it induces a condition of mental repose and the development of a "plastic mind," both highly beneficial to the patient's general condition and also conducive to the production of a regular and rhythmic type of movement. Figure D illustrates the general relaxation position.

CONCLUSIONS

1. The relaxation treatment encourages a mental and a local physical condition conducive to the restoration of normal function in the affected part by instilling into the patient the necessity and ability to rest the central cerebral processes and to develop a "plastic mind."

2. The possibility of producing a maximal movement with a minimal muscle effort lessens the risk of fatigue in a weakened muscle group.

3. The removal of extraneous forces, in particular, gravity, the weight of the limb, and friction, leads to the abolition of fear, with its concomitant involuntary spasm, and to the growth of confidence, with consequent ability to assist voluntarily the restoration processes.

A SAFE METHOD OF DEALING WITH ETHMOIDITIS*

BY

E. A. PETERS, M.D., F.R.C.S.

SURGEON, ROYAL EAR HOSPITAL, UNIVERSITY COLLEGE HOSPITAL, AND BOLINGBROKE HOSPITAL

The dangers of ethmoidal operations are considerable, and are often due to extension of the infection along the perineural sheath of the olfactory nerves or damage to the cribriform plate. There are also the dangers due to an accompanying sinus suppuration. Infection of the frontal sinus, however, gives an indication of its existence by the locality of the pain, and sphenoidal empyema may also be present, a disease dangerous in its closed form and characterized by most indefinite symptoms. Bacteria in the sphenoidal cavity have the power of passing through bone or infecting the meningeal network by some inconstant route.

I would urge that in all cases of ethmoiditis, except simple polypus, radiograms should be taken to obtain information as to the infection of the sinuses, and, if the radiogram is doubtful, that the particular sinus should be drained by the intranasal method. Radiographic pictures of the frontal sinus are usually definite; the evidence of infection of the maxillary antrum is less clear, and that of empyema of the sphenoidal sinus is extremely indefinite. I suggest that primary ethmoiditis operations should, except for simple polypus, consist in removal of the middle turbinal bone with intranasal drainage of the sphenoidal and the maxillary antra. The frontal sinus should be dealt with at the same time by intranasal or external operation if the radiograms and symptoms indicate infection. I am in touch with a patient in whom all six sinuses were opened for early ethmoiditis ten years ago; pus was present in one sphenoidal sinus and in the frontal sinus of the other side. The ethmoiditis has completely subsided.

* Read in the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

The middle turbinal varies very much in structure. In some cases it consists of a lamina, but in others it contains a small or expanded middle ethmoidal cell causing pressure symptoms on the septum when the cell is expanded. It is possible that this pressure when combined with rhinitis may be a factor, for it is this cell type of middle turbinal which undergoes polypoid change; and though the supporters of the "from within theory" may be assisted by some special character of the bone itself, it would appear that it is only in the case of thin laminae of bone, in which periosteum and mucous membrane are closely combined, that inflammation of the mucous membrane leads to osteitis, constituting ethmoiditis. The degree varies from the local change resulting in simple polypus to the common condition of rarefying osteitis with polypi and a varying amount of pus to the extensive form occasionally seen in fevers of acute infection with disintegration of the ethmoid into granulation and pus. Under these conditions the inferior turbinal, consisting of spongy bone, develops hypertrophic rhinitis, and I have seen a middle turbinal of structure similar to an inferior turbinal which merely developed a hypertrophic rhinitis like that of the inferior turbinal.

Removal of Turbinal Bones

Removal of the middle turbinal by Luc's forceps should be carried out either in its entirety by gripping the body of the bone, or by "nibbling" from the anterior end and removing the opened cell. In this way the landmark of attachment of the turbinal is preserved with a view to the opening of cells in the fronto-nasal and agger nasi regions situated at the anterior attachment of the middle turbinal; these are easily opened by the gouge and mallet. It is, as a rule, necessary only to carry out occasional trimmings of polypi under a local anaesthetic from time to time, and to open cells only if the symptoms of discomfort due to closed empyemata appear. Extensive opening of these cells is rarely indicated. Sir StClair Thomson mentions that the opening of the higher cells is fraught with danger. Even removal of the middle turbinal may be a danger.

A man, aged 38, suffered from nasal obstruction. Both the radiogram and the symptoms showed frontal sinus infection. The nasal cavities were filled with oedematous polypi, a small amount of muco-pus being present. A softened middle turbinal was removed from either side and the antrum was opened. On the second day he complained of a severe headache, and died of meningitis. On one side the cribriform plate showed a small erosion from which the softened mucous membrane came away, probably with the turbinal.

This condition would possibly have been fatal in any case, and certainly in any extensive ethmoid removal.

Frontal Sinus

It is rarely necessary to drain this without radiographic or symptomatic indications; if such exist, an intranasal operation should preferably be carried out, special attention being directed to the fronto-nasal and agger nasi cells (anterior ethmoidal group) by applying gouge and mallet to the part immediately anterior to the attachment of the middle turbinal. (This should be done before removal of the middle turbinal.) Infection of these cells is closely interwoven with latent frontal sinusitis, and even with that variety in which the pain is removed by the application of a pledget of wool soaked in 10 per cent. cocaine solution. The maxillary antrum should be drained intranasally in most cases of extensive polypi, an opening being made by Tilley's frontal sinus burr; the aperture can then be enlarged by Luc's forceps. It is usually advisable to remove the anterior end of the inferior

turbinal. The mucous membrane of the sinus is commonly in the same condition as that of the nose; latent or maxillary empyema is excluded by drainage; the consequent effect on the ethmoiditis is good.

Closed sphenoidal empyema gives rise to a series of indefinite symptoms of malaise and pain at the back of the head.

A woman was admitted to hospital for relief of nasal obstruction and removal of septic tonsils. For some years she had had malaise, debility, and catarrhal laryngitis. A radiogram of the chest indicated absence of phthisis, and that of the head showed opacity in the right ethmoid region. No pus was observed on nasal and post-nasal examination. At the operation both middle turbinals were removed. The middle ethmoidal cells were well developed, but did not contain fluid. The septic tonsils were also removed. Three days later the patient developed fever, and a haemolytic streptococcus was isolated from the inflamed pharynx. Anti-scarlet fever serum, collosol manganese, and hypertonic saline were given, and apparently complete recovery took place. Two weeks later a similar attack of fever recurred. Meningitis supervened, and she died four days after this relapse.

In this case neither maxillary sinus nor sphenoidal sinus was opened at the time of operation, as no pus was seen, and it seemed advisable not to expose a feeble individual to further manipulation. The presence of haemolytic streptococci seemed to contraindicate any further intervention in the absence of definite symptoms in the second phase. Yet if the sinus had been opened, her life would have been saved.

Opening the Sphenoidal Sinus

In opening the sphenoidal sinus I usually employ the method introduced by P. Watson-Williams; it is applicable whether the field is obscured by blood or not.

The anaesthetized patient lies on the left side, or sits up. The left forefinger is introduced through the mouth into the post-nasal space, defining the top of the septum nasi. A steel probe introduced through the nostrils touches the forefinger, and is advanced about 1/4 inch anterior and about 1/4 inch from the middle bone. Careful and controlled pressure on the thin bone in front of the dense vomerine ridge perforates the bone or osteum and admits the steel probe into the cavity of the sphenoid. This opening is further enlarged by a narrow gouge, and finally by punch forceps or raspatory. The posterior ethmoid is cautiously opened if necessary. If the middle turbinal has been removed, the enlarged opening of the sphenoid can be observed with a nasal speculum. I have found that Rouge's method gives a better view than lateral rhinotomy when direct manipulation is advisable.

I would suggest that sinus radiography should be carried out in all cases of ethmoiditis, and that the basis of operation should be removal of the middle turbinal, drainage of the sphenoidal sinuses and maxillary antrum; and of the frontal sinuses, if the radiographic examination indicates such a course. This treatment, followed later by removal of polypi under local anaesthesia, and possibly the opening of cells from below the attachment of the middle turbinal, is advised.

A NOTE ON THE TREATMENT OF ERYSIPELAS BY X RAYS

WITH AN ACCOUNT OF THREE CASES

BY

R. HILLHOUSE JAMIESON, M.D., F.R.C.S.ED.

SUTTON, SURREY

AND

F. HERNAMAN-JOHNSON, M.D., D.M.R.E.

RADIOLOGIST, FRENCH HOSPITAL, LONDON; PHYSICIAN IN CHARGE, X-RAY DEPARTMENT, CROYDON GENERAL HOSPITAL

The value of *x*-ray therapy as an agent capable of cutting short the acute stage of erysipelas does not appear to be well known in this country, although it was advocated in America some years ago by Platau, Schlitz, and Collins.[1] An account of the following three cases which recently occurred consecutively in the private practice of one of us (R. H. J.) may therefore prove of interest. The first is quoted as exemplifying the use of local applications and serum, but no *x* rays.

CASE I

A man, aged 63, received a gnat bite on the ear. On May 28th the ear swelled to about three times its usual size; the inflammatory swelling spread slowly over the face, scalp, and forehead. Nothing stopped it, but continuous application of a saturated solution of Epsom salts gave most relief. Ichthyol was disappointing, and once, after its application, the temperature ran up, and the patient had a rigor. Anti-streptococcus serum gave no definite result. Ultimately the temperature dropped after fifteen days of a trying illness—trying to both doctor and patient.

Distressing though the attack was, the temperature did not rise at any time above 101.6° F.; whereas in the two cases next described the temperature reached 103° before *x* rays were applied. Note that the temperature in the first case shows a fall by lysis; in the other two a fall by crisis, immediately following the first application of the *x* rays.

[1] *Journ. Amer. Med. Assoc.*, 1927, lxxxix, 1135.

CASE II

The patient was a man, aged 40. The attack in this instance started sharply, without apparent cause, such as insect bite or an irritated pimple. It soon involved the whole face and scalp, and began to spread down the neck on the right side. The application of Epsom salts solution locally made the patient feel more comfortable. Serum was administered on the morning of the third day, and repeated the two following days. Twelve hours after the last injection of serum the temperature rose to 103°. On the evening of the seventh day of the attack it was still 102.6°. The patient felt very ill, and was very despondent. It was at this point that it was decided to try *x* rays. A portable set was employed, working on the electric light mains. The temperature showed a drop in less than twelve hours to 99.4°, rose to 99.6° the same evening, but the following morning (ninth day) it was normal. *X* rays were omitted on the twelfth day, as the temperature remained normal; but a rise to 99.2° on the thirteenth day seemed to call for a further *x*-ray exposure. After this there was no more fever.

The improvement in this patient's general and local condition after the *x*-ray application was most dramatic. The third case need not be gone into in detail, as it was of very short duration.

CASE III

A married woman, aged 62, suffered from an acute attack of facial erysipelas, following on tonsillitis. The patient was very debilitated, and could not be induced to take nourishment. On the fourth day her whole face and parts of the scalp were red and swollen, and some blisters were present. The disease was spreading. The first dose of *x* rays was administered at 9 p.m. Next morning the temperature was normal, and did not again rise above 98.8°. *X*-ray treatment was given on three successive days.

Comment

We feel that in *x* rays there is to hand a powerful weapon against the disease under discussion. The contrast between the first case, taking its slow and painful course despite all the usual remedies, and the other two, is very remarkable. The two latter were more severe

in type, and in the case of the debilitated elderly patient last described there was considerable risk of the issue terminating fatally if the spread of the infection had not been promptly checked. The remedy is easily applied, as the dosage is very small, and can be obtained from a light portable set, working on the house mains, or even from an accumulator outfit. The small quantity of *x* rays required makes it possible to expose the hair and eyes without risk, as the total dosage, even over several days, need not, on any one area, come near the epilation point, much less that of erythema production. Where an acute inflammation has lasted many days hair may subsequently fall out, and there may be paraesthesia or anaesthesia of portions of the skin. Unless the patient has been warned of this (and possibly even if he has) he will be apt to blame the *x* rays.

How these very small *x*-ray doses accomplish their purpose cannot be stated with any certainty. It can, however, be said that it is not by any direct destruction of the germs. What seems to happen is that local and general resistance is stimulated, so that antibodies are formed where they are most needed. It has been known for a long time that a small dose of *x* rays will often avert a boil, if applied before pus has actually formed. Radiotherapy has been used—again in America—in the acute stages of anterior poliomyelitis. There would appear to be a field for its experimental use in various acute infections. As regards erysipelas, it has passed the experimental stage, and can be confidently recommended in any case which causes anxiety to doctor and patient.

Consideration of space prevents the publication of charts accompanying this article.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

ENTERIC INTUSSUSCEPTION

Enteric intussusception appears to be very uncommon, and some writers say that it only occurs occasionally as an ante-mortem phenomenon in some other diseased state.

A ploughman, aged 47, was admitted to my wards in the Dumfries and Galloway Royal Infirmary on June 8th, 1929, about midnight. Dr. MacMyn of Kirkcudbright reported that on the afternoon of the same day he had found the patient suffering from severe abdominal pain and in a state of collapse. The pain had come on suddenly about two hours previously. There was no history of any such previous attack. Dr. MacMyn expressed the opinion that there was an acute abdominal condition present, and that an immediate laparotomy was indicated.

I saw the patient shortly after admission; he did not then complain of pain, but rather of discomfort "in his inside." He looked tired, and his appearance, pulse, etc., indicated a degree of shock. The bowels had moved normally the same morning. He gave no history of sickness or vomiting, and there was no distension of the abdomen, no evident tumour, no tenderness on firm palpation, and nothing remarkable in the pulse rate and temperature. The heart, lungs, and urine were normal. I did not operate at once, but left word that I should be called if definite symptoms supervened. The patient was fairly comfortable till late the following morning, when he complained of intermittent griping pain, and when I saw him again it was evident that intestinal obstruction was present. There was now some slight distension of the abdomen; the abdominal wall was thin, and the outlines of distended coils of bowel could be seen. There had been no vomiting, and nothing passed from the bowels.

I operated at once, opening the abdomen internal to the outer border of the right rectus, displacing the muscle inwards. There was slight peritoneal effusion, which was unstained. Exploration with the hand revealed a tumour in the pelvis, which on delivery I found to be an intussusception of the small intestine, apparently about the middle of the ileum. About twelve inches of gut were involved. The intussusception was fairly easily reduced, but there were several gangrenous areas towards the apex, which did not recover under copious lavage with warm saline solution. I therefore resected fully eighteen inches of the gut, and restored continuity by end-to-end suture. The patient made an uneventful recovery, except that, notwithstanding the exhibition of morphine, the bowels had to be moved with enemata the day following the operation on account of griping pains. Large scybalous masses were then passed, and doubtless these travelling along the bowel had excited irregular strong peristalsis and intussusception.

There was no indication of a cause of the intussusception in the resected piece of gut, which showed marked swelling of the mucosa.

Dumfries. ROBERT M. GLOVER, M.B., F.R.C.S.Ed.

MEASLES IN A MAN OF 71

In view of the fact that Dr. Arthur J. Hall recorded in the *British Medical Journal* of March 29th, 1930 (p. 586), a case of measles in a man in his sixth decade, the following summary of the notes of a case of measles in the eighth decade may be of general interest.

On November 17th, 1928, a man, aged 71, was admitted to the Broken Hill Hospital complaining of feverishness, running nose, and running eyes for two days. He vomited two days before admission, and had had a cough for a week or two. He had been in contact with a case of measles two weeks before, and on the morning of admission a rash had been discovered on the chest and back. On examination mild conjunctivitis was found, with a heavily furred tongue, scattered crepitations throughout both lungs, and typical measles rash all over the body. The temperature was 101° F., the pulse 104, and the respirations 32 per minute.

As in Dr. Hall's case the prognosis was difficult, the patient not being robust, and being in every respect an "old" man. In addition, his lungs gave every indication of a developing broncho-pneumonia. However, in two days his temperature had subsided, his cough decreased, and the signs in the lungs were less. Several days later the rash had quite faded, and the lungs cleared.

Convalescence was complicated by the conjunctivitis becoming hyperacute, and proving most intractable to treatment. It was four months from the time of admission before the patient could be discharged from hospital, and then it was with a left eye almost blind as a result of the scarring. The right eye showed no permanent damage.

I wish to thank Dr. Ross, surgeon-superintendent of the Broken Hill Hospital, for permission to place this case on record.

O. WESTCOTT FREWIN, M.B., B.S.

Adelaide, South Australia.

BURSITIS AT THE ELBOW

The following notes on a case of bursitis appear worthy of record.

A girl, aged 17, had been employed at a steam laundry, where she worked on a machine, a lever of which she had to move frequently with the left forearm partially flexed and pronated. A cystic swelling developed between the origin of the flexors of the forearm and the bicipital tendon. The swelling was tense, somewhat movable, and when the elbow was flexed or extended gave a rather crepitant feel to the examining thumb. Treatment took the form of several manipulations by the thumb and the application of Scott's dressings. When last seen the swelling was very considerably reduced in size, and was lying between the flexor origin on the internal condyle and the brachial artery. It could easily be displaced internally over the muscle.

Burgess Hill, Sussex.

Reviews

MENTAL DEFICIENCY

One of the most important, as well as one of the most hopeful, books that have yet been published on mental deficiency is *Social Control of the Mentally Deficient*,[1] by Dr. STANLEY POWELL DAVIES of New York. Dr. Davies is primarily a sociologist, and this is well; for though mental deficiency in some of its technical aspects—especially as regards its diagnosis and causation—presents obscure and difficult problems to the anatomist, the geneticist, the psychologist, and the physician, the actual methods of dealing with mentally defective persons are in the main the province of the teacher and of the sociologist. In this book the pedagogic problems presented by the mentally deficient child are not considered, except on the very broad lines in which they must necessarily be related to the sociological picture; but as a well-balanced, judicial, and authoritative summary of existing knowledge on the social aspects of mental deficiency it will not easily be surpassed. The most practical physician must also of necessity be a social worker, and therefore cannot be excluded from this field: correspondingly, Dr. Davies by no means ignores the clinical and the purely scientific aspects of his subject; but, as he says:

"the volume endeavours to present mental deficiency in its social rather than its clinical aspects. It aims to show how the various phases of public opinion and action with reference to the social control of this problem have followed the evolution of scientific thought and knowledge concerning mental deficiency. The more recent trends of thought and measures of control are particularly dealt with as indicating what a modern mental deficiency programme might comprise."

The special point of view of the author, and the peculiar value of his work, may perhaps best be indicated by some quotations from the "Foreword" of Dr. FRANKWOOD E. WILLIAMS, medical director of the National Committee for Mental Hygiene:

"We have come a long way from the period of 'the menace of the feeble-minded' and the Kallikak family, . . . and yet this period was an important one. The data available at that time were correct, but too limited; the hypotheses and social programmes developed as a result of those data were inaccurate theoretically and inadequate socially. . . . Hypotheses, theories, and social procedure have been changed. . . . We have come by a zigzag course to our present views. . . . It is just as easy to-day to be deceived by too little knowledge and to find an easy and obvious solution for a problem too little understood as it was in 1909 or 1912 or 1916; witness the earnest citizens who appear every year before legislatures with programmes that might have looked well in 1909, but that do not incorporate the knowledge accumulated during the past twenty years; the programmes look well, and often impress legislators, if one disregards these twenty years. . . . Davies did not set out to write an account of the development of thought in the field of mental deficiency, but the method he has chosen in presenting his material fortunately accomplishes this without detracting from—in fact, it enriches—the thing he did set out to do; that is, the giving of a clear account of the status of thought and investigation in the field of mental deficiency at the present time. The result is a book from which the new student may learn how not to make the same mistakes that have already been made."

By this admirable method and with this effective purpose Dr. Davies reviews the questions of intelligence tests, of social criteria, of eugenic alarms, of the relation of mental defect to crime and immorality and pauperism. In chapters on the changing concepts of heredity and the newer aspects of behaviour he shows how, as the result of recent experiment and experience, earlier views have to be completely reconsidered and former conclusions profoundly modified. His consideration of the three remedies of sterilization, segregation, and socialization, and their relationship to each other, emerges from this review. He demonstrates the extremely limited sphere of usefulness of the first of these, and some of the administrative difficulties attaching thereto. He shows that segregation by itself produces results that are in many cases disappointing; and a large part of his book is devoted to an exposition of the proper use of the institution and colony as a socializing force, and to the experience acquired by utilizing the school, vocational adjustment, selective environment, and community supervision in securing for mentally deficient persons their safe and proper place in the social order. His conclusions, both as to the success of these methods and generally as to the social and sexual conduct of the feeble-minded in the community when compared with that of other classes of persons, are very hopeful, and appear to be well founded.

[1] *Social Control of the Mentally Deficient*. By Stanley Powell Davies, Ph.D. With foreword by Frankwood E. Williams, M.D. London: Constable and Co., Ltd. 1930. (Pp. xix + 389. 13s. net.)

HUMAN PHYSIOLOGY

The student of physiology has had a new volume by Drs. WINTON and BAYLISS, entitled *Human Physiology*,[2] added to the relatively wide list from which he may choose a textbook. A good book for the medical student dealing with human physiology in a way which will bring conviction to the dullest intellect that physiology is the foundation on which real clinical medicine rests has long been needed. The textbook under review, good though it is in parts, cannot be held to fill the niche. The authors in their preface state that the medical student of to-day is expected to know too much and to think too little. It is true that too much is expected of him in the way of detailed information, but the curriculum as arranged is to blame for allowing him no time for reflection. The authors then go on to suggest that better results would be obtained if the medical student confined his attention to human physiology, "eliminating from his curriculum those parts of physiology which have no immediate bearing on the happenings in the body of man." We have the utmost respect for their ideal, and believe that some genius will eventually achieve (a most difficult task) a volume on the principles of physiology as applied to medicine. The present authors—and we sympathize with them—have fallen frequently from their own high ideal. Admittedly the personal equation plays a large part in determining what has or has not an "immediate bearing on the happenings in the body of man," but it seems to us that much of the long opening chapter on muscle might have been eliminated without loss, as might the long, rather technical, account of the isolated heart-lung preparation. The same criticism may also be directed to the chapter on reproduction. As a chapter it is interesting, but out of proportion. Why devote a full-page illustration of the vaginal smears of the mouse, and several pages of print to the reproductive cycle in the lower mammals, when, for example, spermatogenesis and oögenesis are barely referred to, and the effects of castration on the human male and female are to all intents ignored? Why devote eleven pages to the conditioned reflexes of the dog, when the sensations of taste and smell are not considered, when the electrocardiogram is dismissed in a few words, and when temperature regulation is scantily treated?, All these subjects are of human interest and importance.

We have deliberately stressed some of the weak points so that in a subsequent edition they may be improved. The reader must not presume that *Human Physiology*, as a whole, is poor or second-rate. It is not. The groundwork of the book is excellent; it is well written and nearly always clearly written; it is a promising production.

[2] *Human Physiology*. By F. R. Winton, M.D., and L. E. Bayliss, Ph.D. London: J. and A. Churchill. 1930. (Pp. xiv + 583; 227 figures. 15s.)

ST. BARTHOLOMEW'S HOSPITAL REPORTS

In his "In Memoriam" notice of Sir Anthony Bowlby, with which the sixty-third volume of *St. Bartholomew's Hospital Reports*[3] opens, Mr. Girling Ball shows that the medical school and students never had a more devoted friend, and that Sir Anthony did much in popularizing the study of pathology in the school; for, in addition to his own demonstrations and book on *Surgical Pathology*, he was largely responsible, in the face of much opposition, for the appointment of the late A. A. Kanthack as a whole-time lecturer on pathology at a time when no other medical school in London had taken this step. An account of the new surgical and operation blocks of the hospital, by Mr. T. A. Lodge, F.R.I.B.A., rightly finds a place in the volume. Of the twelve more professional articles, none of which appear to have been published previously, some record single interesting cases, such as Dr. Langdon Brown and Mr. Girling Ball's report on suprarenal carcinoma and virilism in women, Mr. R. Foster Moore and Dr. Geoffrey Evans's case of metastatic carcinoma of the choroid, and Sir Thomas Horder's unusual case of tuberculous meningitis. Other contributors deal with treatment; in cardiac oedema Professor F. R. Fraser recommends digitalis and rest, and then in order diuretin, theophylline, urea, and novasurol, which, however, is more toxic than the others. Drs. R. Armstrong and Johnson make out a good case for the use of Felton's concentrated antipneumococcal serum (Types I and II) in pneumonia, and Mr. R. W. Raven analyses cases of perforated gastric and duodenal ulcers with the object of comparing the results of suture alone and of suture combined with gastro-jejunostomy. Dr. H. V. Dicks deals with the diagnostic and therapeutic value of transduodenal drainage. The diagnosis of bronchial carcinoma is dealt with by Drs. James Maxwell and Nicholson, and Mr. R. Corbett writes on the period of disability in ambulatory fractures. Two articles of special interest are Dr. Mervyn Gordon's philosophical discussion of the problem of the etiology of Hodgkin's disease, and Dr. Wilfred Shaw's essay on the application of ovarian physiology to clinical gynaecology.

PHYSIOTHERAPY

In the preface to their book on physiotherapy,[4] Drs. HOWARD HUMPHRIS and STUART-WEBB point out that comparatively few books exist that attempt to deal with the subject of physiotherapeutics in its entirety, on account of the extent of the ground. They state quite correctly: "To do so, or to attempt to do so, is no easy matter." When a science grows with the development of knowledge there are only two ways of tackling it fully—namely, by a large volume or a series of volumes, to which acknowledged leaders in the subdivisions of the subject contribute full sections; or by a somewhat expanded précis. The authors have chosen the second of these methods, and have been assisted by Mr. Hayward Pinch on radium, Mr. Frank Romer on massage and manipulation, and Dr. Gordon Watson on hydrotherapy and spa treatment. They frankly state that all they attempt to do is to "condense the subject in a simple manner and present it so that it may be readily understood. In doing so, much detail has had perforce to be omitted; but it is hoped that enough has been retained to enable the general practitioner, or consultant, to realize the class of case suitable for physiotherapeutic treatment, and enable the practitioner who has made physiotherapy his specialty to realize the measure appropriate to the malady and to use it with skill and success." It is in the light, therefore, of this position that this book must be read, and consequently the index is of prime importance. Making haphazard selection among conditions about which the general practitioner might want to know whether physiotherapeutic measures were of value, or the specialist whether added information with regard to technique could be secured, the index was consulted as to fractures, gout, hypertrichosis, tennis elbow, radium and keloid, and telangiectasis. To the first and last of these the index gave no reference; for the remainder, one or more page references could be found where interesting accounts were obtainable. The paragraphs on hypertrichosis were particularly practical in the instructions given, including the authors' specific warning against the use of *x* rays in this condition. If the book suffers somewhat from the very restrictions the authors have placed upon themselves, they should be given full credit for their attempt on an extremely difficult task. The pages on the static current make interesting reading, as it is clear that they are "spoken from the heart" of an expert technician.

[3] *St. Bartholomew's Hospital Reports*, vol. lxiii. London: J. Murray. 1930 (Pp. xxv + 277; 19 illustrations. Price to subscribers 15s., to non-subscribers 21s.)

[4] *Physiotherapy, its Principles and Practice*. By F. Howard Humphris, M.D., F.R.C.P.Ed., and Ralph E. Stuart-Webb, M.B., B.S. London: J. Cape. 1930. (Pp. 384; 74 figures. 15s. net.)

BACTERIOLOGICAL TECHNIQUE

The third edition of Professor J. W. H. EYRE'S *Bacteriological Technique*[5] is very similar to the last edition published seventeen years ago. A certain number of new methods are described, and since the majority of the old ones have been retained, there is a slight increase in the size of the book. One chapter has been added, entitled "Methods of testing pathogenesis and establishing active immunity." Technique is so essentially a personal acquisition that it must be very difficult for an author to decide what to include in a book dealing with this subject. He cannot hope to please everybody, and he is liable to sin as much by omission as commission. In the present volume we can find no description of the various methods of performing a microscopical count of bacteria, of preparing vaccines, or of examining faeces, urine, or cerebro-spinal fluid. Comparatively little space is provided for describing the agglutination of bacteria; Dreyer's method, which in its original or slightly modified form is used in most large laboratories in this country, is not mentioned; and nothing is said of the mode of preparation of the various partial antigens which are so valuable in the diagnosis of enteric fever and food poisoning. Similarly the recent methods of estimating the amount of precipitin and precipitinogen in a mixture receive no notice. The bacteriophage is considered briefly, but there is nothing to help the unskilled in the management of the filterable viruses; a chapter on this subject would have been of value. The book contains a considerable amount of useful technical information, and will doubtless prove helpful to certain workers.

NOTES ON BOOKS

In four lectures collected under the title *Individual Psychology and General Medicine*,[6] Dr. F. G. CROOKSHANK seeks to present the essential features of the psychological teaching associated with the name of Adler, and to show how this teaching may be applied effectively in the arts of medical diagnosis and medical treatment. While his space is limited he makes successful use of it, and he presents his argument in an emphatic fashion and illustrates it by individual experiences. He has some words of scorn for the medical outlook which finds a full explanation of disease in the post-mortem room, or of symptoms in the laboratory, yet his real purpose is not to throw aside either one or the other, but to add to

[5] *Bacteriological Technique*. By J. W. H. Eyre, M.D., M.S., F.R.S.Ed. Third edition. London: Baillière, Tindall and Cox. 1930. (Pp. xii + 619; 238 figures. 21s. net.)

[6] Cambridge: *Psyche*. 1930. (1s. post free.)

them in each case a study of the patient's psychology. The patient, that is, is not mere pathological anatomy, nor mere disturbed function; on the contrary, he is the victim also of abnormal mental or emotional activities or defects. Moreover, the three departments overlap, so that events which appear in one may quite possibly find their explanation in another. Hence the need for a complete survey. Altogether the story is a very engaging one, and Dr. Crookshank relates it in lucid and attractive terms. For readers who have no time for large volumes, or who desire a helpful introduction to a subject of increasing importance, these four lectures may be commended.

Some therapeutic novelties of special interest are dealt with in the second part of *E. Merck's Annual Report*[7] for 1930. The need of modern civilization for sedatives is reflected by notices of a large number of new synthetic hypnotics; all are commended by enthusiastic clinical reports, but their very number makes it difficult, if not impossible, to judge their respective merits. Gravitol is a new synthetic compound (dimethylamine of methoxyallylphenol), which is reported to have as powerful an oxytocic action as ergotamine. This compound should attain considerable importance if the claims advanced are substantiated by further clinical trial. Although sanocrysin has had only a moderate clinical success, yet its appearance has led to the introduction of a large variety of organic gold compounds, of which the report contains short accounts. References are given to the extensive literature relating to the more recent biological remedies. Much has been written about liver extract, but no new facts of outstanding importance are reported. Haberlandt's cardiac hormone has also attracted considerable attention, and opinions about its value are evidently very diverse. The ovarian oestrus-producing hormone is being submitted to intensive clinical trials; recent workers report that it is absorbed fairly readily by the mouth, and that the effective oral dose is only about twice the effective hypodermic dose. Positive results in amenorrhoea are said to have followed the continued daily oral administration of about 100 mouse units. Among the original articles in the report is an account of the effects of lack of vitamins A and B, and some excellent illustrations show the effect of vitamin A in producing epithelial metaplasia.

A new edition has lately been prepared of *First Lines in Dispensing*,[8] by H. B. STEVENS and C. E. L. LUCAS. The text bears evidence of revision throughout, and notes on the Dangerous Drugs Regulations have been added.

The full *Transactions* of the Third Session of the Australasian Medical Congress (British Medical Association),[9] held in Sydney from September 2nd to September 7th, 1929, have now been published in a single volume. An account of the opening of the congress and brief notes of the meetings of Sections were given in two of our November issues for that year.

Most of the books written on the problems of auction or contract bridge deal almost exclusively with the subject of bidding, and it is somewhat of a relief to come across a book which confines itself to the actual play of the cards. Once the bidding has ceased, either in auction or contract bridge, the play is the same whatever the game in progress, and in *The Play of the Cards*,[10] by Mr. FRANK ENGLAND and Dr. HOPE REFORD, devotees of the game, whether elementary or advanced, will find sound and reasoned advice as to the technique of play. Even though some of the conventions advocated (such as the lead of the lowest card of three headed by a knave or higher honour, when leading a partner's suit against a "no-trump" call) may not find universal favour, the arguments for and against are fully set out. All the fundamental rules and principles of play have been emphasized concisely in the fifty-three example hands given.

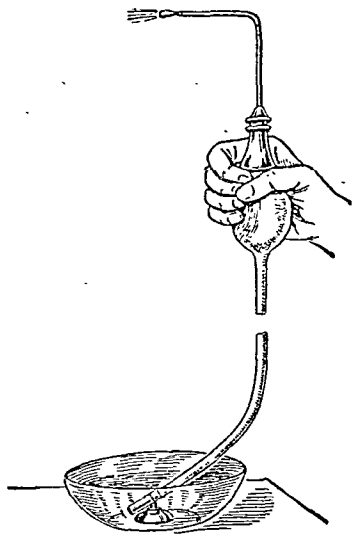
PREPARATIONS AND APPLIANCES

EAR SYRINGE

Dr. W. B. BACON (Withington, Manchester) writes: The accompanying figure shows a new ear syringe that I have had made for me. It consists of a plated ear nozzle with a right-angled bend, and is rigidly attached to a Wingrave's

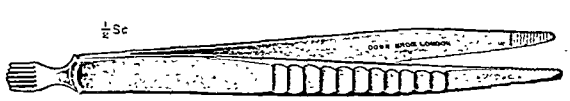


rubber syringe. The whole tube and nozzle is easily detached for sterilization. The force of fluid expelled is equal to that of the piston type of syringe, and, on account of the rigidity of the nozzle attachment, requires only one hand to manipulate; this is the advantage over the ordinary Wingrave's syringe with rubber ear-piece.

This type of syringe has been made for me by Messrs. James Woolley Sons and Co., Ltd., of Manchester.

COMB DISSECTING FORCEPS

Mr. WALTER SALISBURY, M.D., M.S., F.R.C.S. (Northampton) writes: The comb dissecting forceps shown in the accompanying illustration has been made to my design. The comb end is rigid and the blades are flexible. It embodies the principle of the well-known "Kelly's comb," and is most useful in performing the radical operation for cancer of the breast. After the fascia has been divided along the front of the axillary vein with a light touch of the scalpel, the forceps is held in the reverse position, and the comb sweeps the axillary contents away from the posterior aspect of the vein, commencing at the apex of the axilla. Branches of



vessels and nerves are displayed at their origin and clamped or preserved as desired. The proximity of the comb to the handle enables this to be accomplished with ease and precision. I have found the forceps useful for similar types of blunt dissection elsewhere, especially for stripping fascial or omental structures away from vessels, pedicles, ducts, and the necks of hernial sacs. The blades meet at the point only. The instrument serves the double purpose of dissecting forceps and Kelly's comb, so that one instrument less need be taken to a breast operation

It is made in stainless steel by Messrs. Down Bros., Ltd., St. Thomas's Street, S.E.

THE LEAGUE'S INTERNATIONAL WORK FOR HEALTH

On the completion of its tenth year it is being asked in many quarters whether the League of Nations has sufficiently fulfilled, or by common consent can be said to have surpassed, the expectations of the multiplicity of parents, godparents, and well-wishers who acclaimed its birth in 1920. The mere admission that the League is a growing concern, with individuality of its own, however, makes these inquiries somewhat profitless. Evidence accumulates that those who framed the Covenant, and incorporated it in the peace treaties, were by no means in precise agreement about the structure they were founding, the shape it was to assume, the purposes it was to serve, or the material which should be put into it. And if there ever had been rigidly allotted lines by which the League was intended to be restricted, they have been of little account, since that body has seldom hesitated to take the shaping of its future into its own hands. There is justification for the statement, made by the Secretary-General in his foreword to the official compendium recently prepared at Geneva,[1] that the League has shown itself to be dynamic and not static. Different opinions may be held, and different values may be allotted, when the various movements for which the League is responsible come up for assessment. On arbitration, disarmament, international tariff reductions, the system of mandates, and even on the less controversial matters which come before the technical organizations, optimist and pessimist alike can be happy; each will readily find material congenial to the hopefulness or the dubiety with which he approaches the scales. But at least, when Sir Eric Drummond makes us look at the ten years' period as a whole, we can all agree with him that the mere creation of the League and its continued existence during that time is an outstanding landmark in the history of the world, and that the League during these years has greatly grown in its hold on public opinion, on Governments, and on administrations through which public opinion acts.

So far as international work for health is concerned, the League has had some exceptional advantages in this process of choosing its own ground for action. Other technical sections at Geneva—for example, those which deal with economics, with communications and transport, or with labour conditions—have started with, or at least are always dependent on, formal agreements concluded between States; their work has to be thought of mainly in terms of international conventions, the drafting and innumerable conferences they entail, the give and take of negotiations between the representatives of national interests, the uncertainty whether the ratifications of the individual nations will be forthcoming, and the overshadowing doubt whether, after all formalities have been accomplished, the international agreement will work equitably in practice. Formal agreements between Governments are sometimes necessary on health matters, as witnessed by the long series of international sanitary conventions regulating official intercommunication regarding epidemic diseases and the prevention of ship-borne infection; and, in 1921, when it was expected that the International Health Office, already existing in Paris under the Agreement of 1907, would be bodily transferred to the League, much time and thought were given to this aspect of the future health work at Geneva. But when this transfer failed to materialize, convention making, and all that it implies, became quite a subsidiary matter for the League's Health Organization. The system was adopted under which formal agreements between Governments on health matters have continued to be made independently of the League, although its assistance has often been secured by the constitutional liaison which was concluded in 1924 between it and the older organization. It resulted also from this system that while an important section of the Health Committee at Geneva must necessarily consist of medical officers in Government service, that body also comprises numerous medical authorities chosen as experts, who serve either as members of the committee itself or on its various commissions or "expert groups." The Health Committee is called together twice a year, when it advises on work proposed, or approves that which has been done, by the permanent medical branch of the Secretariat, which, under the leadership of the Medical Director of the League, Dr. L. Rajchman, may be regarded as the motor of the present mechanism. Escape from the restrictions of formal conventions, and the possession of a sympathetic committee, are not the only factors that have aided the relative independence of the Health Organization. The primary authorities of the League, the Council and the Assembly, overweighted with controversial and political matters, can always be expected to welcome any public health proposal from which they have expert assurance that international benefit will flow; any such proposals, being pre-eminently world-wide in their scope, make an immediate League appeal. No unreasonable objection has been, or is likely to be, taken on the side of finance, especially when the handsome contributions of the Rockefeller Foundation are taken into account. The appeal is the more effective on account of the simplicity and comprehensiveness of the governing article in the Covenant, by which the League undertakes "to take steps in matters of international concern for the prevention and control of disease."

These considerations may help the reader of this volume to realize how it is that the chapter epitomizing

[1] League of Nations: Ten Years of World Co-operation. With a foreword by Sir Eric Drummond. Geneva: Secretariat of the League of Nations. London: G. Allen and Unwin, Ltd. 1930. (10s.)

the activities of the Health Organization reveals such an astonishing variety of effort for international medical co-operation, in relation both to particular subjects and to the different parts of the world in which they have been dealt with. From the beginning, the Health Organization has devoted much of its energy to necessary standardizing and defining, and the standards for serums, vaccines, and particular therapeutic substances which its Permanent Standards Commission has formulated one by one during the last few years have secured general acceptance. Another regular task has been the supply of world information regarding epidemic diseases. This was begun by the establishment of an intelligence system at Geneva, and at its branch office for the Far East at Singapore; the activities of these information sections have now extended to many other subjects—statistical, administrative, and medical. To these activities must be added the system of "interchange"—a word which has become rather a misnomer, but which denotes that the Health Section of the Secretariat facilitates the visits of medical officers to foreign countries, and has funds on which to draw for missions of inquiry.

The number of expert studies which have been made of individual questions is also very large, a fact testifying to the great willingness with which medical officers and specialists all over the world have responded to suggestions for combined study. Special commissions and conferences have been convened, and notable reports have been issued, on such subjects as the employment of B.C.G., the local incidence of infantile mortality, the occurrence of cancer in different populations, and the effect of radiological treatment, trachoma, trypanosomiasis, and malaria. The question of the choice of appropriate measures to deal with the last-named disease, according to local circumstances and economic conditions, has been under continued investigation by the League's Malaria Commission since 1923, and the report of that body on antimalaria measures in Europe has been one of the most notable, as well as one of the most fruitful, of all the League's undertakings.

The Health Organization appears also to be entering into another and newer stage of its development, by constituting itself an active agent in the promotion of the kind of international spirit which is at the present time particularly in the interests of the League itself. The plea has often been made, and was emphasized at the last Assembly, that the League should in all countries actively support any social, legislative, and administrative action which, to adopt the common formula, "raises the standard of living." This is something more than waiting for difficulties or disputes which require international settlement. It is rather part of the dynamic action to which the Secretary-General refers, and in health matters it takes the form, certainly in the countries more remote from Europe, of giving expert advice, and laying down administrative objectives, in countries which are rapidly changing their social and political structure, and are turning to hygiene as a pivot for modernization and progress. The beginnings already made in this direction include the mission dispatched two years ago to Greece to advise its Government on the creation of a new public health and medical organization, and also other missions which, particularly in connexion with child-welfare, have been sent to Latin American countries. The most considerable example, perhaps, is the attention now being given at Geneva to the creation of a modernized health service in China, under the direction of the Chinese National Government. And, realizing that all these activities sooner or later come round to the question of effective selection and training of personnel, educated to understand what is truth in preventive medicine and to combat the false pretensions which are so often given currency under that name, the Health Organization is at the same time making a considerable effort to provide a clearing-house at Geneva for all the principal national schools of hygiene. On the medical side the League will continue to meet with all good will in connexion with these multifarious initiatives and activities.

THE DIAGNOSIS OF LATENT TUBERCULOSIS

The mortality from tuberculosis in this country has been falling progressively during the past century, and it is pleasant to think that the accelerated rate of decline during the last thirty years may be to some extent attributable to the active measures that have been taken against the disease. But though the mortality is undoubtedly falling, there is no evidence that the frequency of infection is diminishing *pari passu*. The present methods of dealing with tuberculosis consist largely in treating the tuberculous patient, not in combating the spread of tuberculous infection; as a result, though a good many patients are granted a few more years of life, there is no obvious diminution of infection within the community.

From analogy with other droplet-borne infections, such as meningitis, poliomyelitis, and diphtheria, it is not improbable that pulmonary tuberculosis is spread as much by apparently healthy carriers as by patients suffering from the clinical disease. Moreover, only a small proportion of those who become infected ever develop manifest tuberculosis. In the remainder, infection is followed by a focal lesion which ultimately heals. Further infections may lead to a local infiltration, which may or may not undergo retrogression. From the fact that about 90 per cent. of children up to 18 years of age in the large towns of Europe and America react to the tuberculin test, it is clear that at any one time there must always be in the community a considerable number of persons suffering from latent tuberculosis. Such persons are of twofold interest: in the first place they must be regarded as potentially infective, and in the second place they are at any time liable to develop clinical manifestations of disease. Their detection would seem to be the next most important step in the campaign against tuberculosis. This,

we take it, is the main purpose of Sir Robert Philip's Malcolm Morris Memorial Lecture, which appears in to-day's issue. To quote from him: "The chief weakness of the present-day attitude is the disproportionate concentration of attention on pronounced lesions, more especially pulmonary tuberculosis. . . . Attention must be shifted more and more towards the earliest indications of tuberculous infection—not to the neglect of late manifestations, but to their better interpretation and progressive elimination." And again, "If our efforts towards the eradication of tuberculosis from a community are to be effective, it is necessary that we should hunt for the earliest traces of tuberculous infection." To this end Sir Robert Philip advocates the greater use of the tuberculin test and the systematic examination of contacts.

It is a matter for surprise that tuberculosis workers in this country have so largely failed to realize the value of the tuberculin test in controlling the spread of the disease. While the Schick and Dick tests are widely used in the control of diphtheria and scarlet fever, the tuberculin test, which gives information of a different type, it is true, yet none the less of importance, is signally neglected. From the epidemiological point of view, we can think of few things that would be of greater interest at the moment than a systematic survey of school children in different parts of the country to determine the frequency of infection at different ages under different environmental conditions. For such an investigation the graded intracutaneous test should be used, since the information yielded by it is considerably greater than by the von Pirquet test. The tuberculin reaction provides a measure of the incidence of tuberculous infection, and affords some information on the probable activity of the lesion. The actual site and extent of the lesion, however, in latent tuberculosis can be ascertained only by roentgenological examination. If this method were applied to tuberculin-positive school children, it should reveal a certain proportion who were suffering from latent lesions, and who were in danger of developing the clinical disease. Careful watching of these children, with preventive treatment where necessary, should result in a considerable diminution in the cases of active tuberculosis amongst young adolescents. If a further watch could be kept on them after they had left school and were engaged in the serious occupation of earning their living, they might be tided over a period of unusual danger with the minimum number of casualties. That work along these lines is possible is evident from the investigations of Opie and his colleagues in America.[1] Tuberculin tests of school children in Philadelphia showed that 37.7 per cent. were infected with tuberculosis at the age of 5 years, and 90.2 per cent. at the age of 18 years. These figures suggest very strongly that, in spite of the intensive antituberculosis campaign which is being conducted in the United States, there has been no diminution in the incidence of infection during childhood in any way corresponding to the diminution in mortality that has taken place. *X*-ray examination revealed the presence of latent tuberculous foci in the lungs and tracheo-bronchial lymphatic glands of more than 10 per cent. of school children. These lesions varied from massive caseous areas of serious import to firmly calcified foci which had evidently healed. The significance to be attached to them was determined by their size, the activity of the tuberculin reaction, the age of the child, and certain other factors.

Though pulmonary tuberculosis is a relatively incurable disease, it is a strange anomaly that the greater part of the energy and money at present available is spent in attempting to cure patients affected with it. The time has surely come when efforts should be transferred more and more from the therapeutic to the prophylactic field, and when the endeavour should be made, by the careful observation of children and young adults, to prevent the transition of the relatively harmless latent lesions into the infinitely more dangerous lesions of clinical tuberculosis.

POST-VACCINAL NERVOUS DISEASE

The Committee on Vaccination, appointed by the Minister of Health and the Medical Research Council, with Sir Humphry Rolleston as chairman, has now issued a further report embracing observations on the epidemiology and the clinical and pathological character of post-vaccinal nervous disease, together with certain collateral papers.[1] The other members of the committee are Dr. G. F. Buchan, Dr. A. E. Cope, Dr. Mervyn Gordon, Professor J. C. G. Ledingham, and Dr. J. R. Perdrau. Since its first appointment five years ago one member, Dr. F. R. Blaxall, has died; the secretary throughout has been Dr. J. R. Hutchinson. The committee's terms of reference were to inquire and report from time to time (1) on matters relating to the preparation, testing, and standardization of vaccine lymph; (2) on the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination; (3) on the methods of vaccination which are most appropriate to give protection against risk of small-pox infection in epidemic and non-epidemic periods; and to co-ordinate the work of investigation on these questions in this country and abroad. In 1928 the committee presented a report, with recommendations, of which an account was given in our issue of August 11th, 1928 (p. 266). The report now submitted is supplementary to Part II of its predecessor, in which the nature and occurrence of cases of acute disease of the central nervous system after vaccination were studied. It consists, in the main, of a record of the circumstances of ninety such cases subsequently brought to notice, and in respect of the twenty-five fatal authenticated cases it correlates the available clinical information with the post-mortem findings. In addition, four cases presenting a similar symptomatology and pathology, but following variola or measles or influenza, are described, and the report ends with a commentary summarizing the present

[1] Cmd. 3738. Ministry of Health. London: H.M. Stationery Office. 1930. (2s. 6d. net.)

position, from which the opening and closing passages may be quoted:

"An acute nervous disease with a mortality rate of nearly 50 per cent. continues intermittently to appear now here and now there with manifest disregard to the incidence of any known factor other than vaccinia by whatever vaccine produced. It is associated with characteristic changes in the brain and cord similar to those found in the acute nervous conditions occasionally following influenza, measles, and variola. Like them, it is dependent on a precedent infection, but differs in that it follows the infection with great regularity within a definite limit of time. There is nothing in the circumstances of the cases described in this report which has not its parallel in the committee's previous experience."

"Although no particular lymph can be incriminated it is clearly the vaccinia virus, whatever its past history and in whatever medium incorporated, which initiates the nervous disturbance; but why this disturbance should be almost limited to a few individuals only of a particular age group is not known. The grouping of cases in place and time and the tendency to familial incidence are very striking features of the epidemiology, and point, in our opinion, very strongly to the existence of some local individual predisposition in the widest sense of that term."

Further and more detailed reference to the matters discussed in this report and in its valuable appendices will be made in later issues.

FUMIGATION OF FOODSTUFFS

Hydrogen cyanide is at the present time increasingly employed for the disinfestation of rat-infested ships, which may or may not have cargoes of food on board, and for the direct fumigation, either on shipboard or on land, of foods containing moths, maggots, and similar intruders. As the gas is strongly destructive alike of rodent and of insect life, the immediate purposes of its application are, as a rule, satisfactorily attained. The question of its effect upon the foods themselves, whether by spoilage of their quality or by rendering them harmful to consumers owing to the presence of cyanide residues, is discussed in a report[1] by Dr. G. W. Monier-Williams, recently published by the Ministry of Health. The odour of the gas, though characteristic, is neither strong nor irritating, so that the absence of any pronounced taste or smell of HCN cannot be taken as evidence that the fumigated food is fit for consumption. A difficulty arises in relating the cyanide residues in the food to the effective concentration of hydrogen cyanide in the air of the apartment in which the process is carried on, owing to the tendency of the gas to condense on the surfaces of floors, walls, and ceilings. Moist foods in general take up more hydrogen cyanide than dry foods like cereals. The fatal dose of HCN is put by Lehmann at 60 mg., and Jitta states that the maximum quantity permissible in a food is, for an adult, 40 to 50 mg. per 100 grams. Wille records that dates, figs, bacon, and sausages containing, after twenty-four hours' exposure to air, from 278 to 890 parts of HCN per million were able, after further ventilation for a week, to be consumed without ill effects. In a series of examples of various fumigated foods quoted, the residual HCN, after ventilation, was usually less than 20 parts per million, which is well within Jitta's standard above. Experiments described in the report indicate that in foods containing levulose, HCN forms a cyanhydrin, which is stable in air and of questionable toxicity. In foods containing dextrose cyanhydrin is produced only in the presence of alkali. If potassium cyanide is employed in lieu of HCN a cyanhydrin is formed by both the sugars. With regard to the spoilage of foods by hydrogen cyanide, wheat flour appears to suffer no deterioration, but tea, coffee, and tobacco are reported to lose in flavour. Peaches and dessert pears may be shrivelled and discoloured; cooking pears and blue plums are in most cases unaffected. Oranges, with their thick, impervious skins, are usually immune, but cabbages, celery, and lettuce may show severe wilting and become unmarketable. The effect of hydrogen cyanide on living plants depends in part on the concentration of the gas, but more upon the duration of exposure. Since HCN diffuses slowly into the plant tissues, high concentrations for short periods are to be recommended for the destruction of insects. It is noted that in the case of retarded lily of the valley roots and certain bulbs kept in cold storage hydrogen cyanide stimulates growth. As the oxidases are so sensitive to HCN that a trace suffices to arrest their action, the view is expressed that the spoilage by fumigation of fresh fruits and vegetables is to be ascribed to the inhibition by hydrogen cyanide of the enzymes connected with plant respiration. Even without visible deterioration there may be a degree of loss of freshness, possibly involving chemical changes which diminish the nutritive value of the food. As distinguished from the higher plants, bacteria and moulds are relatively resistant to the action of hydrogen cyanide, so that fumigation is of no practical value for their control. The general conclusions of this informative report may be summarized by saying that, if adequate precautions are taken, no serious risk to health is likely to be entailed by the consumption of foods which have been exposed to the action of gaseous hydrogen cyanide. Dosage, however, must be controlled by experienced operators, and high concentrations where possible avoided. As spoilage of fresh fruit and vegetables may result, indiscriminate fumigation of such foodstuffs is to be deprecated, and special care should be taken with those which are known to be most liable to injury.

[1] Reports on Public Health and Medical Subjects. No. 60. The Effect on Foods of Fumigation with Hydrogen Cyanide. By G. W. Monier-Williams. H.M. Stationery Office. 1930. (6d. net.)

NATIONAL INSTITUTE FOR THE BLIND

The admirable work done for blind persons through the agency of the National Institute for the Blind is well set out in the report for the year ending March, 1930.[1] The work is so many-sided that in the space at our disposal little can be said that will give a fair indication of what is being done. One of the activities of the Institute makes a particular appeal to medical practitioners—the training of masseurs. The school of massage was founded in 1915; it is now the one training centre for the blind of this country. It is recognized by the Chartered Society of Massage and Medical Gymnastics, and approved by the Board of Education. One of the reasons for the success that has attended the school is the care with which candidates for training have been selected. Candidates must possess good health and strength, intelligence and tact above the average, and that subtle quality which inspires the patient's confidence. The blind of the right type have

[1] Sixty-first Annual Report of the National Institute for the Blind. 224, Great Portland Street, W.1.

shown themselves excellent practitioners of massage. Arrangements are made with the Hampstead General Hospital for the men students, and with St. George's Hospital for the women students. Holders of the Chartered Society's certificate are eligible for inclusion in the Society of Apothecaries' *Register of Bio-Physical Assistants,* for the initiation of which the British Medical Association was largely responsible. The topographical part of the register was published in the *Supplement* to our issue of November 15th, 1930. This work of training blind masseurs would justify the existence of the National Institute for the Blind. But it is only one branch of its work. The Institute employs many blind persons in the production of articles needed for the blind, and in this way it expends some £20,000 yearly. It is a large publishing firm of Braille and Moon's type books for the blind, and this costs £25,000 a year. It maintains homes and hostels for the blind, special homes for blind infants whose own homes are unsuitable, and, above all, a first-rate public school for blind girls in the college at Chorley Wood; and these institutions cost another £25,000 yearly. It maintains a system of home industries, through which many blind persons are able to earn a living, or some part of a living, and the assistance it gives in this direction costs another £25,000 a year. Those who have interested themselves in the work of the Institute and taken the trouble to investigate its activities are convinced of the efficiency of the management and the economy of its administration.

STAFFING OF MUNICIPAL MATERNITY HOMES

A decision by the maternity and child welfare committee of the Birmingham City Council to exclude private practitioners from attending their cases in its maternity homes at Moseley and Handsworth has led to a strong protest on the part of the local medical profession. At a meeting on December 28th, 1930, attended by more than 150 practitioners in the Birmingham area, the council was asked to reconsider this action. When the intention of the authorities was first made known, a deputation of practitioners, accompanied by the Medical Secretary of the British Medical Association, waited upon the Maternity and Child Welfare Committee, with the result that a definite decision was deferred for fourteen days, but at the end of that time the committee, unmoved by the arguments which had been addressed to it, proceeded with its plans to staff the homes in question with members of the whole-time staff of the health department to the exclusion of the medical attendants of the patients. In making their protest the practitioners are on very strong ground. In the interim report of the Departmental Committee on Maternal Mortality and Morbidity it is pointed out that "the advantages to the general practitioner of facilities for continuing the care of his patient in an institution are undeniable." It is admitted that difficulty would arise from the management and administration of an institution where a large number of practitioners of varying standards of experience and knowledge are in medical charge of the patients, but the report of the Departmental Committee goes on: "The solution of this problem is not easy, and the committee suggest that a method should, if possible, be devised whereby in maternity homes and hospitals unified medical control could be arranged either by the appointment of one practitioner to be responsible for the standard of work of the hospital in co-operation with the practitioner actually in attendance on the case, or by some other means." Moreover, a recent memorandum and circular which the Ministry of Health has issued to all maternity and child welfare authorities states that "local authorities should consider wherever practicable the desirability of affording facilities to private practitioners to attend their own patients in maternity institutions." Many authorities are already acting upon this suggestion, and it can surely be urged that what has been found practicable in other areas is not out of the question in progressive Birmingham. The British Medical Association expressed the same view in the outline, published eighteen months ago, of a national maternity service scheme for England and Wales. One of the principles there laid down was ". . . treatment in the institution being as far as possible continued by the same practitioner"; and, again, "an important and essential part of this scheme is that the doctor should be able to secure the admission of his patients to an institution, and should, where possible, be allowed to treat those of them so admitted." According to the policy of exclusion intended by the Birmingham authority the practitioner who has had ante-natal supervision of the patient, and who has possibly attended her in previous confinements, is denied access to the patient at a time when his knowledge of her case would be of most value. It is, of course, acknowledged that as a corollary to the admission of the general practitioner to the maternity home a certain standard of service must be set up for the home and accepted by him. The scheme which the Birmingham practitioners' deputation proposed, when interviewing the authority, was that the patient should be able to choose her own doctor, that in an emergency any one on a roster of practitioners should be available, and that the service in the homes should be supervised by an expert obstetrician. This plan, which apparently did not meet with favour, would have furnished an excellent opportunity for good team work in which the city health department would have had the supervisory role. The meeting of protest, held under the chairmanship of Dr. O. B. Trumper of Aston, was one of the most representative gatherings of Birmingham practitioners held in recent years. The reasoned resolution which was its outcome is being sent to all members of the city council with a covering letter.

WELFARE OF MERCHANT SEAMEN

In a speech made at a meeting of the Mersey Mission to Seamen at Liverpool, the Poet Laureate said that forty years ago the forecastle of a merchant ship was "a dingy, frowsy, horrible den, disgusting as a pigsty, unspeakable as a dog-kennel." For years voices have been crying in the wilderness against the conditions which Mr. Masefield so succinctly described, but now it would seem that the nations of the world are alive to the fact that the question of seamen's health and welfare demands urgent attention. The second conference at Geneva, called by the Norwegian Red Cross Society, has lately issued its report. According to Dr. Alfred Salter, M.P., chairman of the conference, the first need for the sailor is the establishment of port welfare associations, these to be set up by municipalities, with voluntary assistants from the Red Cross and other

societies. The scope of the work would include the provision of hostels, and the establishment of information bureaux regarding police regulations, licensing rules, and other matters intimately affecting the life of the sailor in port. A suggestion was made that by slightly increasing the contributions to seamen's insurance, hostels could be provided for the men, and this might be within the scope of the National Health Insurance Act, although it is in the category of prevention, and not cure, of disease. Tuberculosis and venereal disease were fully discussed, and Colonel L. W. Harrison made an impressive appeal for the standardized treatment of syphilis. From the statistics provided by the United States of America it was evident that this disease is much neglected by seamen, and a system of regulations and standardized treatment is an urgent necessity. The question of drinking-water on ships came under review, and it was agreed that as a rule water was not sufficiently safeguarded or stored in a sanitary condition. Dr. J. Bohec of the *Ile-de-France* described the recreational opportunities on a large liner whilst in port, and he also spoke of the new seamen's club in New York. The recommendations of the conference include a study of tuberculosis, the establishment of local port committees, universal insurance for seamen, the institution of hospital cabins in ships which do not carry a doctor, instruction in first aid for officers, recreational facilities, and the provision of libraries. It is hoped that the work of the conference will be the starting point of national activities in order that the seamen's lot may be a much happier one than hitherto.

METHODS AND PROBLEMS OF MEDICAL EDUCATION

The eighteenth series of the generously illustrated accounts of leading departments, brought out at intervals since 1924 by the Rockefeller Foundation under the name of *Methods and Problems of Medical Education*,[1] contains thirty articles, eleven of which deal with physiological or biochemical departments in centres so far apart as Oxford and Capetown, Patna and Buenos Aires, Alberta and Belgrade. Six articles are devoted to descriptions of various departments of the University of Michigan at Ann Arbor, including those of physiology, physiological chemistry, out-patient departments of medicine, surgery, and ophthalmology, and the heart station, which occupies a suite of eleven rooms. Two institutes of pathology are described, that at Würzburg by Professor M. B. Schmidt, and that at Belgrade; further, Professor W. G. MacCallum of the Johns Hopkins University gives an account of his method of taking photographs of gross pathological specimens. Professor A. Gosset supplements the account he previously gave, in the twelfth series of these papers, of his surgical clinic at the Salpêtrière, and expresses his conviction that a surgical clinic should consist of at least two hundred beds. The Ferens Institute at the Middlesex Hospital, exclusively devoted to research in oto-laryngology, is fortunate in having Dr. A. A. Gray, formerly of Glasgow, as a whole-time research worker; the account of this institute is appropriately accompanied by a description of Dr. Chevalier Jackson's bronchoscopic clinic at Temple University Hospital, Philadelphia. Drs. D. L. Edsall and J. C. Aub give an account of a recently introduced method of teaching third-year students preventive medicine in the clinic at the Harvard Medical School. Professor J. K. Robertson of Queen's University, Kingston, considers the problem of teaching physics to medical students, and recommends more instruction directed to the understanding of radiology.

PATHOLOGICAL MUSEUM AT THE EASTBOURNE MEETING

In connexion with the Ninety-ninth Annual Meeting of the British Medical Association at Eastbourne next July, a museum of scientific exhibits and pathological specimens is being organized by a special committee. It is proposed to arrange the material under the following heads: (1) exhibits bearing on discussions and papers to the various Sections; (2) specimens and illustrations relating to any recent research work; (3) instruments relating to clinical diagnosis and pathological investigation; (4) individual specimens of special interest, or a series illustrating some special subject. It is also proposed to make an effort to gather together a series of exhibits—*x*-ray and other photographs—relating to milk-borne human diseases. Photomicrographs will be preferred to microscopic slides. The committee wishes it to be understood that the above are only suggestions, and if there is any subject in which members are specially interested and can supply appropriate specimens, these will be welcomed. The museum will occupy a central position and will be easy of access. The committee desires to enlist the hearty co-operation of all members, and will be glad to hear from those who are able to contribute. Every care will be taken of specimens, and the contents of the museum will be insured. So far as possible arrangements will be made whereby exhibitors may have an opportunity of demonstrating their specimens. Communications should be addressed to Dr. E. A. Fiddian, honorary secretary, 5, The Goffs, Eastbourne.

RADIUM DISTRIBUTION

The first annual reports of the National Radium Trust and the National Radium Commission, issued together as a Blue Book in October last, were reviewed in the *Journal* of October 18th (p. 656). The report of the Trust dealt with purchases of radium up to March 31st, 1930, whereas the Commission's report extended over a period ending August 31st, 1930. By the end of March 9.215 grams of radium were in hand, 5 grams had been ordered, and the purchase of 3 grams was under negotiation for the preparation of radon. Through the courtesy of the Radium Commission we are now able to give more recent figures. The amount of radium delivered up to January 5th, 1931, by the supplying company was approximately 20 grams. The amount of radium delivered by the Commission to centres, and in full clinical use, was approximately 15 grams.

The King, on the recommendation of the Minister of Health, has appointed Sir C. Hubert Bond, M.D., and Dr. Arthur Rotherham to be senior commissioners of the Board of Control, under the provisions of Section II of the Mental Treatment Act, 1930.

IMPERIAL CANCER RESEARCH FUND

SCIENTIFIC REPORT

The ninth scientific report of the Imperial Cancer Research Fund, which has lately been issued,[1] is separated by seven years from its predecessor, which appeared in December, 1923. The director of the Fund, Dr. J. A. Murray, F.R.S., has brought together in it twelve original contributions, two reprints from the *British Journal of Experimental Pathology*, and two from the *Biochemical Journal*; he has rendered available the most recent information about filterable tumours of the fowl in their relation to malignancy, and certain other aspects of the etiology of cancer. Considerable value is added to the report by the fact that the method of illustration employed is that known as "pseudoscopic," the figures being so prepared and arranged in couples as to be capable of being viewed through a stereoscope of the ordinary prismatic type, or, even without this instrument, by diminished or increased convergence of the eyes, resulting in combination of the pairs of pictures.

Filterable Fowl Tumours

The first article, by Drs. J. A. Murray and A. M. Begg, contains a description of the histology and histogenesis of a filterable endothelioma of the fowl. Careful study of the early stages in its development revealed the gradual transformation of the endothelial cells of the capillaries into malignant cells. It has been shown that these filterable tumours can be produced specifically by the inoculation of material from which cells were absent. Lymphocytes were seen emigrating from the capillaries and accumulating in the inoculated area; they quickly increased in size, and presented all the appearances of macrophages. Mitotic proliferation followed, and a definite parenchymatous stage appeared to have ensued. Further experiment is being conducted to test the validity of the hypothesis submitted consequently, which emphasizes the conception of cancer as a disease of reacting tissues. In Dr. Begg's work on a filterable fibrosarcoma of the fowl, which had been recorded in the *British Journal of Experimental Pathology*, the primary growth and first transplanted tumours had the structure of a simple, hard fibroma. There was, however, an increase in the rate of growth during subsequent transplantation, and the tumour became softer and more cellular, a sarcomatous type of formation resulting. The tumour could ultimately be propagated by cell-free filtrates and by dry material, but it is admitted that such may originally have been the case.

Dr. W. Cramer reports on the possibility of transmitting mammalian neoplasms without the intervention of living cells. He adopted the procedure of repeatedly freezing and thawing sarcoma and carcinoma cells, and found that when this process was repeated four times, subsequent attempts at the transmission with it of carcinoma uniformly failed, although positive results were frequently obtained in the case of sarcomata. Biological differences seemed, however, to be exhibited by the cells of different sarcoma strains, and even by cells of one and the same sarcoma strain when tested at different times. It is not certain whether these differences are to be interpreted as variations in the resistance of the cells to death by freezing, or as indications of the possibility of neoplasm transmission without the intervention of living cells. Dr. Cramer points out, nevertheless, that the experimental evidence of previous workers, in so far as it has been based almost entirely on negative results with cell-free material from mammalian carcinoma cells, has not so conclusively proved the absence of an agent separable from the living tumour cell as has hitherto been supposed.

Drs. Cramer and L. Foulds, in another contribution, discuss the effect of repeated freezing on the transmission of the Rous sarcoma No. 1 of the fowl, and their experimental results tend to approximate these filterable tumours to the mammalian sarcomata. With both groups the inoculation of frozen material gives at one time positive results, while at another negative results ensue, the difference between the two groups being only one of degree. Dr. H. G. Crabtree, who investigated the effect of repeated freezing and thawing on the oxygen absorption and glycolysis of normal and of cancerous cells, reports that normal cells are more profoundly affected than malignant cells, but he could trace no significant difference in this respect between carcinoma and sarcoma cells. A paper by this author originally published in the *Biochemical Journal* (1928) is reprinted. In it an account is given of the examination of the carbohydrate metabolism in several strains of mouse tumours by Warburg's manometric technique. The general conclusion drawn is that the magnitude and relationships of the respiratory and glycolytic processes, which were thought by Warburg to be characteristic of malignant tissues, are not specific for these, but are a common feature of pathological overgrowths. The carbohydrate metabolism of tumours is, moreover, influenced to some extent by their environment.

Experimental Carcinogenesis

Dr. Cramer discusses the local resistance of the skin to the development of malignancy, in a paper which has been reprinted from the *British Journal of Experimental Pathology*. He demonstrated the existence in a tar-painted area of regions of varying resistance to the development of malignancy, and drew an analogy with occupational skin cancer in man. Evidence is adduced that the process of carcinogenesis is not continuous, but is based on two phases: a long-lasting process inducing in epithelial cells a condition of "potential malignancy," which is kept in check by the local resistance of other tissue elements; and, secondly, a local breaking down of this resistance, permitting an immediate malignant development of the potentially malignant cells. Dr. J. A. Murray reports in another article that no clear evidence of resistance to tar-cancer induction was obtained in sixty-one mice with spontaneous mammary cancer, and in two with previous tar cancer. No significant differences were noted, whether there was recurrence or not. The result is provisionally attributed to the use of a very active preparation in the testing course of tar painting, so that the differences between the series of animals were obliterated.

Nerves and Cancer

Dr. R. J. Ludford has endeavoured to discover whether anything resembling the innervation of the normal skin of the mouse was traceable in malignant tumours of epidermal origin. Using de Castro's modification of Cajal's staining method, he was able to show that there was no specific innervation of cancerous growths, and that the occasional presence of nerves in carcinomata was due either to the persistence of pre-existing nerves or, more usually, to the inclusion of nerves within the cancer in consequence of the invasive character of its growth.

Nuclear Origin of Malignancy

Dr. Ludford discusses at length the hypothesis that alteration in the nucleus is associated with the development of malignant changes. He describes the chromosome formation in cancer cells without spindle development, and reports a new type of abnormality of mitosis in

[1] London: Taylor and Francis, Red Lion Court, Fleet Street. 1930. (20s.)

certain transplantable tumours. Support is thus given to the view that two distinct processes are involved in mitosis, the formation and autonomous splitting of the chromosomes being distinct from the development of the spindle; the co-ordination of these two series of events is essential for normal mitosis. In a comprehensive and critical paper on the somatic cell mutation theory of cancer, he discusses its relation to etiology and treatment, and suggests that such a hypothesis leaves out of account what has been discovered in relation to the filterable tumours of the fowl.

HEALTH OF THE SCHOOL CHILD

SIR GEORGE NEWMAN'S REPORT

In his annual report for 1929 on the school medical service* the Chief Medical Officer of the Board of Education reiterates the statement that the foundation of this service is the systematic and routine medical inspection of all the children in attendance at public elementary schools, whether sick or well. Last year the total number of children inspected was 2,737,327, or 55.8 per cent. of the average attendance. In addition, there were re-inspections of 1,909,469.

The practice of medical inspection is being applied in a limited yet increasing degree to the pre-school and the post-school sections of the community. Attempts are being made to bridge the gap between the time when the child attends the maternity and child welfare centres and when he enters school. Sir George Newman suggests that, provided the local education authority concurs, parents should be encouraged to bring their young children for medical inspection at the school when they are requested to attend inspections of their pupil children. This, he considers, would be advantageous, especially in rural districts where health centres are few and far between. Medical inspection of the majority of the pupils in secondary schools is now a statutory obligation, and in many areas medical examination of pupils in technical and continuation schools is also carried out. The practice is extending widely to commercial firms through their welfare departments, and is a valuable supplement to the work of the certifying factory surgeon.

Besides the systematic medical inspection of school children there are inspections by the school nurses for conditions of uncleanliness. The improvement that has been brought about by this procedure has been maintained. Over 14 million inspections were made, or 2.9 per child. The number of children found unclean was 701,300, compared with 850,842 in 1926, 777,498 in 1927, and 712,721 in 1928.

Findings of Medical Inspections

The percentage of children found to be suffering from definite defects (excluding dental disease and uncleanliness) requiring treatment was 20.8, compared with 20.1 in 1926, 20.6 in 1927, and 20.7 in 1928. Defects of vision head the list with 86 per 1,000, closely followed by tonsils and adenoids with 66. Skin diseases were responsible for 12, deformities 9.7, organic heart disease 2, nervous diseases 2, pulmonary tuberculosis 1.2, and non-pulmonary tuberculosis 0.8.

Special attention had been paid to the incidence of malnutrition, particularly in areas where there has been prolonged industrial depression. The figures for routine inspections indicate little increase in the country as a whole. Reports from the individual stricken areas reveal only a slight rise in the number of definitely undernourished children, but many remark on an increase in the number of children of subnormal physique—the so-called "borderline" cases. The percentage of children with subnormal nutrition in Rhondda for the past six years is stated to be: 5.21, 6.13, 6.93, 5.02, 5.12, 3.33, while the corresponding figures from Aberdare for the same period are: 4.9, 3.7, 4.7, 3.4, 8.9, 8. There is evidence that in certain areas in South Wales the results of the prevailing hardship and privation are becoming more evident among the entrants than among the elder children. In the majority of areas not subjected to exceptional industrial distress the nutrition of school children appears to be improving.

Medical Treatment

Treatment carried out under the school medical service is mainly prophylactic, and is directed towards the removal and correction of defects which, if untreated, might lead to serious conditions in later years. Schemes for the medical treatment of the children have now been developing for twenty years. Provision for minor ailments, tonsils and adenoids, and eye defects is nearly complete, and arrangements for orthopaedic treatment are rapidly extending. The establishment of centres for the supervision of children suffering from rheumatism is a recent development. Organization is easy in populous centres, but difficult in sparsely populated rural areas. In the latter the advantage of combining the public health services under one head is becoming apparent. The same nurse may be engaged in infant welfare work, school work, and cleanliness surveys, as a visitor under a tuberculosis scheme, in duties under the mental deficiency authority, and possibly as a sick nurse. Gloucestershire is cited as an example of the close co-operation of public medical officers, private practitioners, specialists, and members of the nursing profession in forming one co-ordinated service, and reference is made to the article on this subject by Dr. Middleton Martin in our *Supplement* of February 8th, 1930.

The *x*-ray treatment of ringworm of the scalp is being adopted by an increasing number of authorities. Although the cost is greater than that of chemicals, the loss of grant through long periods of absence from school is avoided. There has also been a marked reduction in the number of cases requiring treatment in areas where *x* rays are in use. Arrangements for the treatment of defective vision are made by all local authorities except one. There are 606 clinics and 66 hospitals doing the work. Cases dealt with numbered 216,496, and 11,342 were treated through other agencies. Where spectacles were ordered 91.1 per cent. are stated to have been obtained. It is urged that the visual acuity of all children with glasses should be tested once a year; children with myopia should be re-examined every six months if the condition is progressive.

In Leicestershire the school oculist differentiated the returns of vision conditions in children attending well-lighted schools and those where the lighting was defective. In the former there were 6.7 per cent. wearing glasses and 5.6 per cent. suffering from eye-strain; in the badly lighted schools the figures were 8.7 and 10.7 respectively. Dr. Inman of Portsmouth found that 25 per cent. of the children attending the eye department required no active treatment. They were mostly "nervous" children, and he discussed the question whether their symptoms were produced by disharmony of mind rather than of body. The report urges the early ascertainment of cases of squint and appropriate treatment. Local authorities are urged to consider arrangements for dealing with cases of defect in pre-school years, since the earlier the treatment the better the chance of curing the defect and of preventing the affected eye from becoming amblyopic.

* The Health of the School Child. Annual Report of the Chief Medical Officer of the Board of Education for the year 1929. London: H.M. Stationery Office. 1930. Pp. 153. (2s. net.)

Facilities for operative treatment of tonsils and adenoids are provided by 271 authorities in 478 hospitals and 78 clinics. Operations were performed in 97,518 cases, or 54.8 per cent. of the number referred for treatment. The report states that operations should be carried out only by surgeons with special experience and holding special qualifications in this branch of surgery. Overnight retention of the patient after the operation should be the rule. In Derbyshire Dr. F. J. Burke noted the manner in which catarrhal conditions cleared up after removal of enlarged tonsils and adenoids. Mr. J. A. Keen of the Leicester Education Authority made a study of the substitutes recommended for operation—breathing exercises and nasal drill, treatment by drugs and attention to general health, treatment by vaccines, local treatment of the nose and throat, treatment by radium and *x* rays. Some of these, he concludes, have a limited value, but their general adoption would result in a high proportion of failures. Some of the methods are unsuitable for children; others cannot be applied to adenoids, while a few are by no means devoid of risk. He is definitely of the opinion that no satisfactory substitute for removal by operation has yet been discovered.

Special facilities for the examination and treatment of aural disease are provided by 88 authorities, while treatment of middle-ear disease by ionization is carried out in forty-five areas. The arrangements usually take the form of a consultation clinic, attended periodically by an aural specialist, where certain forms of treatment are given, and the provision of available hospital beds for patients needing operation. In the prevention of otitis media the importance of efficient control of epidemics, especially of scarlet fever and measles, is emphasized. Much can be done to lessen the incidence and severity of aural sequels from such disease by the appointment of aural surgeons on the staffs of isolation hospitals and by the more extensive hospital treatment of cases of measles. In the routine treatment of otitis media due consideration must be given to the condition of the nasopharynx. The removal of tonsils and adenoids may go a long way towards effecting a cure in a substantial percentage of cases.

Exceptional Children

The complete ascertainment of exceptional children, defined as those who on account of mental or physical disabilities cannot derive full benefit from education in a public elementary school, depends on the co-operation of many workers, official and voluntary, in the education field. First, there is the school teacher, who should bring before the school doctor any child who is not making normal progress. For children suffering from disabilities so severe as to prevent them attending school the school attendance officer must be relied upon. Health visitors, school nurses, and members of voluntary committees can play their part. The work of the school doctor in dealing with gross defects is straightforward. More difficult problems arise where there is only retardation of two or three years. He must determine whether this is caused by mental dullness, mere backwardness following ill-health and absence from school, or defect of the special senses. The child whose retardation is due to innate mental defect presents similar problems. Can he be instructed in an ordinary class, or is a special school needed, or must notification to the mental deficiency authority be employed as a last resource? Mention is made of the work of the child guidance clinic. Such a clinic does for mental hygiene what the school clinic does for physical hygiene. Its primary duty is the ascertainment, study, and correction of minor abnormalities, which, if left to themselves, may eventually lead up to gross aberrations of conduct, delinquency, and crime. A recent report of the clinic, established by the Jewish Health Organization of Great Britain, contains the following statement:

"We believe that material is now accumulating for the clearer definition of types of nervous children, and the possibility of marking off the class from which delinquency springs is becoming less obscure."

(To be concluded)

THE NEW YEAR HONOURS

As announced in last week's *Journal*, the list of New Year honours was issued as a special supplement to the *London Gazette* of December 30th. It includes the names of the following members of the medical profession, to all of whom we offer congratulations.

Baronet

Sir JOHN ROSE BRADFORD, K.C.M.G., C.B., C.B.E., M.D., D.Sc., F.R.C.P., F.R.S., President of the Royal College of Physicians of London, consulting physician, University College Hospital.

Companion of Honour

Miss JANE HARRIET WALKER, M.D., L.R.C.P.I., L.R.C.S.Ed., founder and medical superintendent of the East Anglian Sanatorium, Nayland, Suffolk; founder and first president of the Medical Women's Federation.

K.C.B. (Military)

Lieut.-General HAROLD B. FAWCUS, C.B., C.M.G., D.S.O., D.C.L., M.B. (late R.A.M.C.), K.H.P., Director-General, Army Medical Services.

K.C.V.O.

ASHLEY WATSON MACKINTOSH, M.D., LL.D., F.R.C.P.Ed., Honorary Physician to H.M. Household in Scotland, Emeritus Professor of Medicine in the University of Aberdeen.

Knights Bachelor

ERNEST GORDON GRAHAM LITTLE, M.D., F.R.C.P., M.P., Member of Senate, University of London, since 1906.

JAMES SMITH WHITAKER, M.R.C.S., L.R.C.P., Senior Medical Officer, Ministry of Health.

AMBROSE EDGAR WOODALL, M.D., M.Sc., F.R.C.S., medical superintendent of the Manor House Hospital, Golders Green.

C.B. (Military)

Major-General LAWRENCE HUMPHRY, C.M.G. (late R.A.M.C.), V.H.S., Deputy Director of Medical Services, Western Command, India.

C.I.E.

Major ERIC EDWARD DOYLE, D.S.O., I.M.S., Inspector-General of Prisons, Bombay.

Lieut.-Colonel JASPER ROBERT JOLY TYRRELL, M.B., I.M.S., Chief Medical Officer in Central India.

Lieut.-Colonel HUGH WILLIAM ACTON, I.M.S., Director, School of Tropical Medicine and Hygiene, Calcutta.

Lieut.-Colonel IAN MCPHERSON MACRAE, O.B.E., M.B., I.M.S., Inspector-General of Prisons, Bihar and Orissa.

C.B.E. (Civil)

Miss LOUISA MARTINDALE, M.D., B.S., president of the Medical Women's Federation and vice-president of the Medical Women's International Association.

Major ERNEST BLECHYNDEN WAGGETT, D.S.O., T.D., M.A., M.B., B.Ch., honorary consultant in diseases of the throat, nose, and ear to Queen Alexandra Military Hospital.

Miss AGNES CATHERINE SCOTT, M.B., Chief Medical Officer, Women's Medical Service, India, and secretary to the Countess of Dufferin's Fund (dated December 15th, 1930).

M.V.O.

MARCUS ANTONIUS JOHNSTON DE LAVIS-TRAFFORD, O.B.E., M.D.

O.B.E. (Military)

Lieut.-Colonel SAMUEL GEORGE STEELE HAUGHTON, M.D., I.M.S., officer commanding Combined Indian Military Hospital, Kohat, India.

O.B.E. (Civil)

FRANCIS EDWARD FORWARD, F.R.C.S., Class I Prison Medical Officer, Home Office.

Captain HADJI DABIRUDDIN AHMAD, Bengal Medical Service, teacher of anatomy, Campbell Medical School, Bengal (dated December 15th, 1930).

Lieut.-Colonel JOHN WILLIAM MCCOY, I.M.S. (ret.), civil surgeon and superintendent of jail, Sylhet, Assam (dated December 15th, 1930).

ARTHUR HUTTON MCSHINE, M.D., nominated unofficial Member of the Legislative Council of Trinidad and Tobago. For public services.

JOHN RICHARD COOK STEPHENS, M.R.C.S., L.R.C.P., West African Medical Staff, Nigeria.

M.B.E.

HOMEWELL LYNGDOH, Assam Medical Service, civil surgeon, Nowgong (dated December 15th, 1930).

GEORGE ALVES VINCENT, M.B., medical superintendent, St. Ann's Lunatic Asylum, Trinidad.

Kaisar-i-Hind Medal (First Class)

Miss MARY RONALD BISSET, M.B., in charge Zenana Baptist Mission Hospital, Bhiwani, Punjab.

GRAHAM COLVILLE RAMSAY, O.B.E., M.D., employed on malarial research work by the Ross Institute, Assam.

PROMOTIONS

Royal Naval Volunteer Reserve.—Surgeon Commander JAMES B. RONALDSON, V.D., M.D., to be Surgeon Captain. Surgeon Lieut. Commander JAMES LORIMER, V.D., M.B., to be Surgeon Commander.

Royal Air Force Medical Service.—Wing Commander WILLIAM TYRRELL, D.S.O., *M.C.*, M.B., B.Ch., D.P.H., to be Group Captain. Squadron Leader KENNETH BIGGS, *M.C.*, M.R.C.S., L.R.C.P., D.P.H., to be Wing Commander.

England and Wales

Supervision of Foodstuffs and Drugs

A report on the Sale of Food and Drugs Acts, containing extracts from the annual report of the Ministry of Health for 1929-30, and an abstract of the reports of public analysts for 1929, has been published by H.M. Stationery Office (3d. net). It states that the number of samples analysed in England and Wales in 1929 was 133,584, an increase of 4,550 on the total of the previous year. Of these, 7,260 samples, or 5.4 per cent., were reported to be adulterated or not up to standard. This proportion is slightly less than in 1928, when the percentage was 5.8. Offences against the Public Health Regulations relating to preservatives, etc., in food decreased by 246; the majority of the adverse reports were concerned with sausages and other meat products. More than half the samples examined during the year were milk samples, 7.8 per cent. being found below standard or adulterated; the corresponding percentages for 1928 and 1927 were 8.2 and 6.9 respectively. Nearly 600 samples were taken immediately after milking, under conditions which precluded the possibility of adulteration, and 206, or 35.6 per cent., were found to be below standard. In commenting on this high percentage the report points out that, if such samples had been excluded, the percentage of milk samples reported as adulterated or not up to standard would have been reduced from 7.8 to 7.5. A few samples of graded milk, although satisfying the legal requirements in regard to bacterial purity, contained less than 3 per cent. of milk fat. In one report the opinion was expressed that fat deficiencies in graded milks are somewhat frequent, and appear to be caused by the methods employed in bottling. Examination of nearly 11,000 samples of butter revealed adulteration in 1.4 per cent., a vendor being fined £20 for the addition of boric acid. Several samples of cheese were reported to have been contaminated by tin-foil wrapping. It is suggested that manufacturers should realize the potential danger to health involved in this practice by providing, for example, an inner covering of grease-proof paper. Other foodstuffs inspected included cream, margarine, lard, bread, flour, jam, marmalade, vinegar, spirits, and beer. During the year 5,544 samples of 109 different varieties of drugs were examined, 254, or 4.6 per cent., being found to be adulterated, compared with 5.6 per cent. in 1928. A sample sold as distilled water proved on inspection to be water from the ordinary public supply, and the vendor was fined 10s. and 10s. 6d. costs.

Facilities for Medical Practice on Housing Estates

The London County Council has been making inquiry into the facilities afforded to medical practitioners on its housing estates. In the earlier stages of the development of the cottage estates no provision was made for the accommodation of practitioners other than the letting of houses to doctors who were prepared to take them at economic rents. This class of accommodation, however, was not quite suitable for the needs of a resident doctor, although it might suffice for a branch surgery. It was decided, therefore, to allocate a number of sites to be offered for letting on building lease to doctors prepared to erect their own residences. Ten doctors at Becontree have availed themselves of this facility, four at Watling estate, three at Downham, two at St. Helier, one at Bellingham, and one at Wormholt. In addition, more than fifty practitioners established in the vicinity of the various estates are known to attend the Council's tenants. No complaints have been received as to shortage of practitioners. The Council had already decided that there should be absolute freedom of choice of doctor by the persons living on the estates, and, further, that no restriction should be placed on the ability of a doctor to secure a site for his premises. The only difficulty experienced by applicants desiring to set up in practice appears to be that inquiries for sites are usually received at an early date in the development of the estate, and therefore a considerable time elapses before sites are available for building. It appears that eight doctors have established surgeries in or over shops erected by the Council's lessees, seven of these being branches of older-established practices; but the committee which has been inquiring into the matter sees no reason to suppose that accommodation over a shop is, in itself, inadequate or unsuitable for a doctor's surgery. On the general question, while realizing the importance of adequate medical facilities, and of freedom of choice of doctor, the committee is satisfied that there is no need at the present time for any general revision of existing provisions.

Medical and Dental Treatment of London School Children

In dealing with the arrangements for the medical and dental treatment of school children for the year commencing April 1st next, the London County Council has had in mind the accommodation at the institutions and hospitals transferred under the Local Government Act which could be utilized for the treatment of school children. It appeared that the most urgent help which some of the hospitals could give was by way of in-patient treatment for enlarged tonsils and adenoids, and arrangements to this end are being furthered. It has also been decided to establish a small centre for throat in-patient treatment at the Eastman Clinic (Royal Free Hospital). With regard to rheumatism, it is reported that the scheme, in force since 1928, for the establishment of supervisory centres to which parents of children suspected to be rheumatic or requiring observation for rheumatism might apply periodically for advice has been highly successful. There are at present six supervisory clinics at school treatment centres and five at hospitals. It has been decided to arrange for a number of acute and subacute cases to be admitted to Queen Mary's Hospital, Carshalton, and Highwood Hospital, Brentwood, and additional accommodation amounting to 350 beds will shortly be available at Carshalton. The provision of further supervisory centres at the Royal Free Hospital, St. George's Hospital, and Lewisham Centre is proposed. It is hoped that new school treatment and infant welfare

centres on the Downham estate and at Putney will be ready in 1931. The number of cases for which provision is made for the year 1931–32 includes: 41,820 eye cases, 21,380 ear, nose, and throat cases, 664 ringworm cases, 78,980 cases of minor ailment, and 147,950 dental cases, an increase on the total of 8,690 cases, and the cost of the arrangements will be £117,084.

Ireland

Unclean Milk Peril

Although there is complete Government control of milk supplied to creameries in the Irish Free State, under the Dairy Produce Act of 1924, there is no Government licensing, grading, or classification of milk, and no efficient control of the cleanliness and wholesomeness of milk sold for human consumption, whether raw or pasteurized. In a communication to the *Irish Times*, Professor Joseph Bigger, M.D., pathologist in the medical school of Dublin University, stated that there was no legal control of milk in the Free State. At present, he declared, firms advertise a special grade of milk, but that meant nothing. As regards the general condition of milk he thought there had been some improvement in Dublin, thanks to the work of Mr. Dolan and others, but it was a great drawback that no power existed to go outside the city to get at people sending unclean milk to Dublin; incidentally, this was one of the weak spots in the committee's report. The question had recently arisen in Liverpool, where the health authority objected to milk coming into that city from Cheshire, since there were no proper control and powers of inspection at the source. Such authority was urgently required in the Free State. It was absurd that milk going to the creameries to be made into butter was protected by many more precautions than milk that was to be drunk. Professor Bigger went on to point out the great danger to child life from bovine tuberculosis, which was chiefly responsible for the non-pulmonary tuberculosis in bone, gland, and abdomen. He referred to the fact that in 1929, of the cows slaughtered in the Dublin abattoir, 32.5 per cent. were affected by tuberculosis. These were old animals, but the high percentage of tuberculosis led to the inference that there was a good deal of infection among the younger animals too. In emphasizing the need for Government action, he gave some figures demonstrating what had been accomplished in New York by energetic methods. In that city pasteurization had been introduced in 1914, and the death rate from abdominal tuberculosis in infants under 1 year fell from 20 per 100,000 in 1913 to 6 in the following year. The statistics indicated that since 1923 the death rate from non-pulmonary tuberculosis among infants and children up to the age of 15 had been practically constant—a fact which proved, in his opinion, that bovine tuberculosis had become an extinct disease in New York as a result of the control of milk supplies. He considered that the problem of a clean milk supply could be tackled only in two ways. One was to secure herds of cows free from tuberculosis; the other was compulsory pasteurization and, in the grading of milk, provision for the cleanliness of animals, workers, and utensils. No producer, he thought, should be allowed to send out milk unless he had a steam sterilizer and a proper cooler. It was also important to have some legal control of terms, as in England, where there was certified graded milk. Clean milk meant safe milk, especially for infants and young children. He was of the opinion that the Royal Dublin Society, which had done so much for the improvement of cattle in other directions, might be of enormous help in securing the improvement of the milk supplies of the community.

Free State Health Commission and Opticians

The Irish Medical Secretary recently addressed a letter to the National Health Insurance Commission pointing out that an optician had stated in the press, in support of a claim for State registration of his association, that the Commission had approved the employment of opticians by approved societies for the supply of glasses to insured persons without prescriptions from ophthalmic surgeons. In answer to the statement that the Irish Committee was of the opinion that "opticians" should be allowed to supply glasses only on the prescription of ophthalmic surgeons, the Commission replies that the adoption of this suggestion would have the effect of precluding a large number of insured persons from participating in optical benefits because: (*a*) the number of ophthalmic surgeons is limited, and they are available only in the cities and larger towns of the Saorstat; (*b*) the money available for optical benefit is limited, and the provision of optical appliances on the recommendation of qualified opticians affords the widest field for the benefit of the insured persons. The Commission remarks that it is well aware of the arguments for and against the present procedure in connexion with the administration of the benefit, but that in sanctioning the schemes at present in force it has satisfied itself that in existing circumstances they afford the best method of dealing with the matter. It adds that, prior to adopting the present procedure, it made several efforts to secure a satisfactory scheme by interviewing recognized opticians, but failed on account of their somewhat indefinite position. It may be mentioned that the Department of Local Government and Public Health has constituted throughout the Irish Free State an adequate panel of ophthalmic surgeons for the school medical inspection scheme, the requirements of which are on a more extensive scale than ophthalmic benefit under the National Health Commission.

Correspondence

LEPROSY IN THE BRITISH EMPIRE

SIR,—In the annotation in your issue of December 27th, it is suggested that the British Empire Leprosy Relief Association might "consider more carefully" the introduction of *H. wightiana* and *H. anthelmintica* into leprous areas of British Africa. May I mention that the seeds of these trees, with directions for their cultivation, have been supplied since 1925 to forty British possessions in all quarters of the globe, including fourteen African areas. Fiji has about 1,000 trees, some of which have already fruited. Queensland has grown young trees and distributed them to neighbouring areas, Zanzibar has flourishing plantations, and Uganda and Swaziland have a number of trees, as have the West Indies. We are yearly distributing further supplies of the seeds, and hope before long to ensure adequate local supplies of the oils extracted from the seeds in all leprous regions of our Empire. Unlimited supplies of the *H. wightiana* oil are also obtainable from South-West India and of the *H. anthelmintica* from Siam, so no shortage is possible.

I may also point out that the old vein difficulty following intravenous injections of sodium hydnocarpate has been eliminated now that this preparation in the form of "alepol" given intramuscularly has been proved to be very effective in leprosy as the result of the use of some half a million doses supplied by our association to the African colonies alone during 1929, at a cost per dose about one-twentieth that of the ethyl esters, which we had not sufficient funds to distribute in the required quantities. Moreover, Dr. Bray's recent paper on leprosy in Nauru Island showed a 40 per cent. reduction in the leprosy cases

there within three years, through the adoption of my plan of frequent examinations of the small population to detect and clear up all new infections in the earliest stage, not one of which has gone on to the more advanced and highly infectious nodular form. This success has furnished the means rapidly to reduce leprosy wherever all contacts of cases can thus be examined repeatedly.

In conclusion, I desire to express my gratitude for the consistent support of the work of our association by the *British Medical Journal*.—I am, etc.,

LEONARD ROGERS,
Honorary Medical Adviser, British Empire Leprosy Relief Association.

London, N.W.1, Jan. 3rd.

RECENT WORK ON YELLOW FEVER

SIR,—In your leading article on December 20th, 1930, under the above heading, reference is made to the work of the Yellow Fever Commission (West Africa), of which I was chairman, and it is suggested that the fact that its reports and those of the investigators were issued during the war may account for the little appreciation which they have received. One of my objects in now writing to you is to make known, as possibly an additional reason, that all the copies not distributed at the time of publication were lost, and in spite of much search have so remained until quite recently. During the interval I have received repeated applications for copies. They have now been found, and may be obtained on application either to Dr. Stanton, the chief medical adviser to the Secretary of State, Colonial Office, Downing Street, or to the Crown Agents for the Colonies, Millbank.

The fourth and (unfortunate addition) "final" report, written in the earlier years of the war, shows that had any urgent representations, made early in 1919, that the Commission should be reappointed, been approved, it is highly probable that the great credit of having discovered that the monkey could be infected with the virus of the disease, and so be used as a test of its presence in the human subject, would have belonged to the Commission. That discovery marks an epoch in the history of yellow fever. Dr. (now Sir) Andrew Balfour, a member of the Commission, had informed us of a tradition in Trinidad that a great mortality among the red howler monkeys there had frequently been observed to precede an outbreak of yellow fever. In Appendix III. (p. 269) of the fourth report is a scheme for a research on yellow fever:

Attempted Transmission of Yellow Fever to Monkeys and Other Animals.

A. . . .
B. . . .

This scheme was drawn up by Dr. A. Connal. The first steps taken by the Commission on its reappointment would have been to follow up this clue on the lines laid down in detail in the scheme. At my suggestion Dr. E. Hindle, on appointment as Beit Fellow in tropical medicine, at once took steps to obtain some red howler monkeys, but they are very delicate animals, and since then none have arrived alive in this country. We have only just learned that Dr. Aragao in Rio has succeeded in infecting these animals with the virus of yellow fever, thus proving that we were on the right tack. I do not know whether Dr. Adrian Stokes, of lamented memory, was aware of our "scheme," but it would have been an obvious step on the part of anyone, before proceeding with such a research, to make himself acquainted with the recent literature on the subject.

The discovery by members of the Rockefeller Commission of the endemic areas, of whose existence I felt confident, is a very valuable addition to our knowledge of the disease, and it is on these areas that preventive work should now be concentrated. It would be interesting to know whether the percentage of natives in and around Dakar who are immune to yellow fever is less than 100.

The numerous laboratory infections which have recently occurred in this country and elsewhere, leading to illnesses so diverse in clinical type as to be unrecognizable except for the fact that they have conferred immunity to the disease, enable us to understand how impossible it was seventeen years ago for our investigators to identify among the natives a disease which could be the means of keeping the infection alive during the often long intervals between its appearance in epidemic form among the Syrians and Europeans. Some time ago I wrote to you in opposition to the suggestion that Dr. Young had been infected when making the post-mortem examination on Dr. Noguchi, but it is evident that the handling of a monkey recently dead from yellow fever is quite a different matter, and is fraught with grave danger, and that even to touch its blood, or that of a patient during the first three days of the illness, with the unprotected hand, may be followed by death. It is satisfactory to know that we shall hear no more of the term "West African yellow fever," against the use of which I also made a protest.—I am, etc.,

JAMES K. FOWLER.

Beaulieu Abbey, Hants, Jan. 3rd.

INCUBATION PERIOD OF MEASLES

SIR,—The interesting point which emerges from Dr. Lempriere's paper in the *Journal* of January 3rd is, in my opinion, not that the incubation period of measles may under certain conditions exceed a maximum of sixteen days, but that it should have in so many instances exceeded that maximum in so small an outbreak as he describes. In my experience a period of sixteen days is not infrequently exceeded. I have records of 116 cases in which the incubation period was noted, and the following table shows the variations:

Days (at least)	No. of Cases	Days (at least)	No. of Cases.
6	1	14	8
7	5	15	10
8	7	16	7
9	9	17	1
10	17	18	2
11	18	19	4
12	16	20	4
13	6	25	1

In the majority of cases the incubation period was probably longer than the period stated in the table, for most of the patients were known to have been exposed to infection for periods varying from one to three days. The incubation period is reckoned to be from the time of cessation to exposure to the appearance of the first symptom. It may safely be stated that in nearly one-third of the cases of measles the incubation period is *fifteen days or longer*. In twenty-five of the cases the length of exposure to infection was under twenty-four hours; the incubation periods in these cases were as follows:

Days	Cases	Days	Cases
7	1	14	1
8	1	15	3
9	2	16	1
10	3	17	1
11	3	19	2
12	5	25	1
13	1		

In one of the twelve-day cases the length of exposure was 11½ hours; in one of the fifteen-day cases, 8 hours; and in the twenty-five-day case, 2 hours only. This last is the longest incubation period I have met with; the shortest did not exceed eight days, and was not shorter than seven.

In the 1928 edition of the "Code of Rules," issued by the Medical Officers of Schools' Association, it is stated

that the incubation period is seven to fourteen days. The latter figure I think to be too short. Perhaps Dr. Lempriere will now agree with me. When I was in charge of a fever hospital I always enforced a quarantine of twenty-one days before I declared a ward to be safe for the admission of new patients.—I am, etc.,

Hemingford Abbots, Hunts, Jan. 4th. E. W. GOODALL.

CAUSATION OF MENTAL DEFICIENCY

SIR,—As the British Medical Association has just appointed a committee of inquiry into the causes of mental deficiency, it may be of interest to your readers to know that my committee, in conjunction with the Medical Research Council and the Darwin Trust, has recently appointed a whole-time research medical officer and a social investigator to inquire into the causes of mental deficiency. We have felt the need of this inquiry for some time, but could not afford to take it up till the generosity of Lady and Miss Darwin, and the considerable help of the Medical Research Council, made it possible.

The arrangement was come to with the Medical Research Council and the Darwin Trust months before we knew of the Association's intention, and the appointment of a research medical officer was made some time ago. The first piece of research is to be a minute inquiry into the physical and mental characteristics, the home environment, and the family histories of the 1,400 patients in this institution. The investigators are beginning work this month. The research medical officer is Dr. L. S. Penrose, and the social investigator is Miss Newlyn, who has been working for the Devonshire Voluntary Association on Mental Welfare for the last five or six years.—I am, etc.,

Colchester, Dec. 30th, 1930. F. DOUGLAS TURNER, Medical Superintendent, Royal Eastern Counties Institution for the Mentally Defective.

THE METABOLISM OF TUMOURS

SIR,—Your leading article in the *Journal* of December 20th, 1930, in which you discuss the importance of the researches of Professor Warburg on the metabolism of tumours, rather bumps the scale on the side of the metabolic theory of the genesis of these growths. As you state, oxygen and carbohydrate are the sources of growth energy, and glycolysis, actual or potential, appears to be closely connected with growth. But in concentrating on glycolysis one is apt to forget the part played by the fats in metabolism. Carbohydrate and fat combustion go hand in hand; fat will not oxidize without carbohydrate, and, conversely, carbohydrate will not burn without fat. It follows that any apparent error in carbohydrate metabolism may not occur *per se*, but must arise from some fault in fat metabolism.

For some time I have been struck by the fact that cancer frequently develops in people who have at some preceding period in their lives suffered from glycosuria of the non-pancreatic type. The odd feature about this glycosuria is that it does not always persist; sugar may be found in the urine sometimes occasionally, sometimes only once. I have yet to come across a patient with true pancreatic diabetes developing cancer. This to my mind is a point of great significance, for in the non-pancreatic type there is no lack of insulin to prepare the sugar for combustion, and still it is not burnt, but escapes via the renal threshold. Why is this? It can only be because the fatty acids have not been sufficiently unsaturated by the liver ferments and lipase to be set alight. It is no use trying to light a fire with dried paper and wet sticks. Combustion of fats and carbohydrate is therefore incomplete, with the result that there is present a superabundance of fatty acids, and perhaps, in consequence, formation of saponins—bodies which by their solvent action on the lecithin and cholesterin of the cell are extremely irritating. The alteration of surface tension which they induce has a profound influence on the division of cells, as proved by numerous experiments.

Dr. W. H. Martindale endeavoured to prepare for me a preparation of lipase which I could inject into cancer patients, but found it impossible to get one which was sterile and yet retained its activity. I am now injecting a solution of glycerin intravenously in a case of scirrhus of the breast in which operation has been refused. The hope is that glycerin might combine with the fatty acids and form innocuous fat. As one could not find in print anywhere the slightest information as to dosage and limits of toleration, the initial dose was a small one—namely, 10 minims in a 10 per cent. solution—but this was rapidly increased to a 50 per cent. solution—1 drachm of glycerin and 1 drachm of boiled tap water. Distilled water will cause a rigor unless perfectly fresh, owing to the presence of dead bodies of bacteria. One must be careful, too, not to miss the vein, and thereby inject the solution into the surrounding tissues, otherwise pain for some hours will ensue.

Learning from Mr. R. Thomas of Lever Bros., Ltd., that small quantities of tin, among other bodies, act as a catalyst and assist the synthesis of fatty acids and glycerin into fat, I inject at the same time intramuscularly 2 c.cm. of stannoxyl. The results so far are most encouraging. The patient states that the breast is no longer "fast," and she can move it freely, also the "bone" in it has disappeared. Local application consists of glycerin to the retracted nipple.—I am, etc.,

Upholland, Dec. 27th, 1930. J. THOMSON SHIRLAW.

TREATMENT OF TETANUS

SIR,—Dr. Grove-White's memorandum on this subject, published on November 15th, 1930 (p. 821), impels me to record a case of tetanus which I myself successfully treated about eighteen months ago in Ibadan, Nigeria. The special interest of this case lies in the fact that cure was effected by injection of serum into the cisterna magna, an expedient which I adopted, as a last resource, after several intrathecal injections by the usual lumbar route had proved ineffectual. These are the facts.

A native, aged about 30, was brought to my hospital with half his hand blown off by the explosion of a shot-gun. I treated his hand, but neglected to give him a prophylactic injection of antitetanic serum. Exactly one week later he began to complain of slight stiffness in the jaws and neck, and in a very short time the symptoms of tetanus were well established. I commenced treatment on the following lines:

(*a*) Intrathecal injections of serum. (This line of treatment was suggested to me by a colleague, who said that he knew of a case of tetanus that had been cured in Lagos by intrathecal injection of a massive dose of serum in concentrated quantity.)
(*b*) Subcutaneous injections of dilute carbolic acid.
(*c*) Chloral and bromide four-hourly.
(*d*) Chloroform inhalations as required.

I cannot now recall how long this treatment was persisted in, but several injections of serum (totalling, perhaps, 40,000 units) were given by the lumbar route. Still the condition of the patient continued to grow worse. Trismus was intensified, the spasms became more frequent and more violent, and a very marked degree of wasting was reached. My colleague and I decided that the case was hopeless. Now, one thing attracted my attention, and it was the fact that the patient's lower limbs had become relatively flaccid, whereas they had previously been nearly as rigid as the trunk; in conjunction with this sign, I recalled that on the last few occasions on which we had injected the serum we had failed to draw off cerebro-spinal fluid. Coupling these two facts together, I hazarded a guess that, for some such reason as traumatic occlusion of the subarachnoid space, the serum had been prevented from travelling upwards, and that there was

still a possibility of cure if only we injected the serum into the upper end of the theca. Accordingly, as a forlorn hope, I injected 16,000 units through the occipito-atlantoid membrane. I gave this injection at 10 p.m., and in order the better to observe its effects, I simultaneously stopped all other treatment. Well, the patient had one spasm during that night, and it was the last spasm he ever had.

The trismus and the stiffness of neck and trunk disappeared only by slow degrees over a period of about two weeks. It was interesting to observe the gradual increase from day to day in the range of movement of the jaw; or to watch the transition of the trunk and neck muscles, through varying degrees of rigidity, from iron-like hardness down to normal tone. The last muscle group to attain to normal was that at the back of the neck on the side corresponding to the injured hand.

The case clearly shows that tetanus in its very latest stages can be cured by the injection of serum (16,000 units) into the cisterna magna.—I am, etc.,

Manor Hamilton, co. Leitrim, Dec. 22nd, 1930. T. O'CARROLL, Late W.A.M.S.

SIR,—In view of the memorandum on the treatment of tetanus recently published in your columns (November 15th, 1930, p. 821), may I be permitted to describe the following case in a young boy, who had fairly severe tetanus and recovered after receiving large doses of chloretone and antitetanic serum?

H. K., a well-developed boy of 6, was admitted to hospital on July 27th, 1930, with an acute osteomyelitis of the upper end of the right tibia. He was stated to have fallen off his scooter three days previously, and to have injured his knee. An abrasion was present just below the knee.

Under chloroform anaesthesia the medullary cavity was exposed along the upper half of the tibia. Purulent matter was found welling out of the Haversian canals and in the medullary cavity. The gutter left in the bone was irrigated with peroxide and packed with flavine gauze. The anaesthesia created some difficulty owing to spasm of the respiratory muscles, the real significance of which was not then appreciated.

Next day his temperature, which was 103.4° F. before the operation, remained at the same level, his pulse rate quickened, his general condition appeared worse, and he became delirious. The state of the leg itself appeared perfectly satisfactory, and physical examination apart from the nervous system was negative. It was observed, however, that he kept the left leg flexed, and any attempts at extending it were fiercely resented. There was marked rigidity of the neck muscles, generalized hypertonicity, and moderately severe trismus, though not sufficient to prevent the taking of fluid nourishment. Kernig's sign was positive, and every few minutes a risus sardonicus passed across his face. The negative result of the examination of his cerebro-spinal fluid confirmed the diagnosis of tetanus.

He was given 15 grains of chloretone in olive oil per rectum, and 15,000 units of antitetanic serum intramuscularly the same evening. These were repeated twelve-hourly for five doses, so that he had 75,000 units of serum and 75 grains of chloretone in two and a half days. For the first twenty-four hours there appeared little change in his condition, and he nearly sprang out of his cot several times, owing to the violent contractions of his rectus abdominalis muscles. At the same time he had transient attacks of cyanosis, evidently due to the spasm of his respiratory muscles. During the subsequent thirty-six hours, however, the trismus gradually disappeared, the spasms diminished in violence and frequency, and on the morning of July 30th, when his temperature fell by crisis to 99.2°, the state of his nervous system was practically normal. He was given a final dose of antitoxin, 10,000 units intramuscularly and 5,000 units hypodermically, the following day, and the chloretone was continued in 5-grain doses by the mouth for three days subsequently. His cardiac condition gave cause for some anxiety, and he was put on brandy and digitalis four-hourly on the morning of his crisis. Apart from a pleural friction rub at the left base, which lasted only a few hours (on August 1st), convalescence from the tetanus was uninterrupted.

One swallow does not make a summer, but, all things considered, this case seems to point to the advisability of administering large doses of antitoxin, and to the apparent efficacy of the intramuscular route; the absence of any unpleasant reaction was noteworthy. Further to the value of chloretone as a depressant of reflex excitability, Cushny states that as a sedative to the irritability of the spinal cord this drug is superior even to morphine, and the absence of any untoward effects on the respiratory or cardiac centres seems to make it an ideal sedative in this disease.—I am, etc.,

Lowestoft and North Suffolk Hospital, Dec. 23rd, 1930. DOUGLAS BELL.

RESULTS OF TREATMENT OF CANCER

SIR,—My letter printed in the *British Medical Journal* of November 29th, 1930, had for its object not, as Sir Gilbert Barling asserts, "to depreciate the Birmingham surgeons," but to learn the truth. Sir Gilbert Barling objects to my statement that the Campaign report ignored the total number of cases operated on after he has just stated that "the total number of cases was 799," a figure appearing nowhere in the report. He terms my figures imaginary, but his quarrel here is with the authorities of the Queen's and Women's Hospitals, from whose records the figures are taken. I have verified these figures to-day. At the Queen's Hospital, for the five years 1910–14, 220 amputations of the breast were performed, 90 per cent. of which were for cancer—202 cases. At the Women's Hospital, for the eleven years 1910–20, 478 amputations of the breast were performed. In the Women's Hospital records no analysis of the cases is given, but it is a logical inference that, as in the Queen's Hospital records, 90 per cent. would be for cancer—430 cases. Of Sir Gilbert Barling's 799 cases, 632 are thus accounted for (or very nearly), leaving a balance of 167, which we are invited to believe represents all the cases operated on for cancer of the breast at the General Hospital during a period of eleven years, and at the Queen's Hospital during a period of six years.—I am, etc.,

Birmingham, Dec. 22nd, 1930. A. A. RUSSELL GREEN.

GLYCERIN AS A SURGICAL DRESSING

SIR,—I am much interested in Dr. Ronald Mackinnon's letter on glycerin in midwifery in your issue of December 6th, 1930, and it has induced me to state my experience of the use of glycerin as a very beneficial dressing in many of the common conditions of inflammation and suppuration which we meet in general practice.

As far back as June 19th, 1909, Dr. A. Ogier Ward recorded in the *Journal* his treatment of boils and carbuncles by carbolic glycerin on pledgets of cotton-wool. He stated that he owed this method to his old teacher, the late Dr. John Duncan of Edinburgh. It was carbolic glycerin that Dr. Ward was advocating, but in the last paragraph of his letter he says that it may be that glycerin alone would suffice. I took the hint contained in that paragraph, and for several years treated boils and carbuncles by a pad of cotton-wool soaked in pure glycerin alone, by dropping pure glycerin into all the cavities as they appeared, as well as by packing the crater or craters with small pledgets of cotton-wool soaked in pure glycerin. The external pad was covered by gutta-percha tissue and a bandage applied loosely. This treatment proved to be very effectual.

Strangely enough I continued for a long time to use this treatment for boils and carbuncles without it occurring to me that it might be equally beneficial in

other septic conditions. A very bad whitlow was responsible for suggesting the extension of the glycerin treatment, and I soon found myself treating all kinds of septic wounds and sores by pure glycerin, applied either on cotton-wool or on boric lint, and in each case covered by guttapercha tissue or oiled cambric. These septic wounds and sores healed very nicely under the glycerin treatment; a noteworthy fact was the absence of the bleaching and maceration of the skin, and a reduced tendency for pustules to form round about the sore or wound, both of which conditions are so often found when ordinary wet dressings are used over a prolonged period. The only disadvantages of the treatment appeared to be the sweet, mawkish odour of the dressing, the oozing of the glycerin into the bandage, and the somewhat pale, flabby appearance of the granulation tissue. However, I continued to use the pure glycerin method because of its undoubted efficacy, until one day, while dressing a septic finger, I damped the lint with water so that the glycerin would permeate it more rapidly, as pure glycerin is apt to run off such fabric instead of soaking into it. This modification I feared might not be so useful in preventing bleaching and maceration of the skin, but the sequel showed that the change of technique presented no disadvantage. I had applied the glycerin fairly liberally to the damp lint, but on subsequent occasions I used less and less glycerin and still found that bleaching and maceration did not occur.

During the past fifteen years my regular method has been to apply only a few drops of glycerin to the first inch or inch and a half of a strip of damp lint about 6 inches by 1 inch, in the case of a septic finger, and then apply the lint bandagewise, cover it with guttapercha tissue, and secure by a roller bandage. In other cases, as on the arm or leg, the glycerin is poured on to the damp lint in a little serpentine stream, no attempt being made to cover the lint evenly, and the dressing is by no means flooded by glycerin. More recently I have applied the method tentatively in cases of eczema, and have found it very satisfactory, but I am not yet in a position to say to what extent it can be usefully employed in such cases. On several occasions I have dressed stitched perineums in the same manner with perfect results.

I am enthusiastic in my praise of glycerin as an ideal treatment of such conditions as have been mentioned above, and the point I wish to stress is the absence of bleaching and maceration of the skin, which means that less opportunity is given to the germs to multiply. Those who have used glycerin as a dressing must have noticed this fact, but so far I have not seen it recorded. Whatever may be the explanation, I have failed to find this method to be inferior to the use of such antiseptics as 1 to 40 carbolic lotion, in so far as the clearing up of the sepsis or the healing of the wounds is concerned.

Glycerin is not classed among the antiseptics, and when used in conjunction with antiseptics is regarded only as a vehicle, and while there is no doubt that it inhibits bacterial growth, yet when one considers the very small proportion of glycerin that is present in the wet-boric-lint-cum-glycerin method it is scarcely feasible that the beneficial result is due to a definite antiseptic action. It may be merely a case of giving the tissues a good chance to avail themselves of the *vis medicatrix naturae* by keeping the wound or sores in a congenial environment without irritating or destroying the tissues, and by preventing the entrance of additional bacteria to the wound. In this connexion it is noteworthy that in a very virulent bacterial infection the application of antiseptics is most disappointing in so far as any speedy amelioration is concerned, and when improvement does occur it seems to take place without regard to the presence of the antiseptics. In other words, a method which merely nurses the tissues instead of attacking the bacteria seems to be quite as efficient—if not more efficient. There are possible exceptions, as in the value of magnesium sulphate as a wet dressing in erysipelas, and also in boils, carbuncles, and other septic conditions, but on the other hand these boils, carbuncles, etc., can be treated just as well by glycerin alone, and perhaps glycerin alone might be as effective as magnesium sulphate in erysipelas. Of course it must be admitted that magnesium sulphate also is not one of the recognized antiseptics, and it may exert, so far as I know, only an inhibitory action on bacterial growth.

Dr. Alex. MacLennan, surgeon to the Glasgow Western Infirmary, recorded in the *Journal* of December 10th, 1910, two cases of tuberculous peritonitis in which he employed pure glycerin intraperitoneally. He used about one pint of pure glycerin. He remarks that "in desperate cases of general peritonitis I think glycerin in large quantities has a most beneficial action, but it must not be forgotten that it is highly toxic." In view of my finding that a comparatively weak solution of glycerin is so beneficial in septic wounds and sores I think that much less than a pint of glycerin diluted with water would probably prove quite as effective, and at the same time avoid toxic symptoms. Glycerin is undoubtedly very hygroscopic, and so is magnesium sulphate, but in the comparatively weak solutions in which I have employed both it can scarcely be maintained that the good results are due in the main to the hygroscopic power.—I am, etc.,

Glasgow, Jan. 1st. DAVID KYLE, M.A., M.B., CH.B.

INTESTINAL MYIASIS

SIR,—I was greatly interested in the account of a case of intestinal myiasis reported by Dr. Shrewsbury in your issue of December 20th, 1930 (p. 1043). His remark that reports of cases are infrequent prompts me to put on record the following case, which I encountered in 1925 while practising in Southern Nigeria. I have no notes now available, but the facts so far as I can recall them are these.

The patient was an adult African woman; her husband was cook to a neighbouring European household, and she often helped in the preparation of food. She complained of passing small white moving bodies in her motions, and these on examination proved to be fly larvae, which were present in considerable numbers. I do not recollect that diarrhoea was a very marked feature. The larvae were larger than those described by Dr. Shrewsbury, and from their naked-eye appearance, and from the fact that the adults of the species were present in large numbers around the patient's house, they were diagnosed as the larvae of the bluebottle fly. From the information given me I came to the conclusion that infection was by contamination of the food by the flies.

I recollect that the patient was much distressed at the appearance of the larvae, but became very offended when I pointed out to her that the cause was most probably to be found in the first place in the general uncleanliness of her own habits and of her immediate surroundings. The condition quickly cleared up, but whether as a result of the purgative or the advice as to general cleanliness and sanitation, which were both given, I hesitate to say, though I doubt whether the latter was greatly heeded. Incidentally, I would remark that my experience leads me to believe that the European in the Tropics will find that the greater part of the danger to health which he encounters is to be found in his own kitchen, and careful supervision there will amply repay him.—I am, etc.,

THOS. C. LONIE, M.B., Ch.B.

London, S.W.11, Dec. 30th, 1930.

HIERONYMUS FRACASTORIUS

SIR,—The most interesting review in your issue of December 13th (p. 1015), prompted me to read Professor W. C. Wright's translation of *De Contagione*. The translator's conclusion that the term "*nervi*," used by Fracastorius (Book II, Chapter X, on rabies), cannot be interpreted as nerves is supported by the designations "*Nervus intriconatus*," "*Nervus contritus*," and "*Nervus incisus*" for certain muscles by Laurentius Rusius (early fourteenth century). Other veterinary writers of the period described diseases of the tendons ("*nervi*")—for example, "*Nervous feritus*" (literally, struck tendon), whence the fifteenth century French "*nerfferu*" (*nerf-ferure*) and the modern French "*nerf mauvais*" and "*nerf trenchiez*"—that is, laceration of the flexor tendon of a fore limb by the shoe of a hind limb, known in modern English veterinary surgery as "over-reach." (Vide L. Moulé: *Histoire de la Médecine Vétérinaire*, deuxième periode, deuxième partie, p. 97, Paris, 1900.)

It would appear probable that Fracastorius derived some inspiration on the etiology of rabies from his predecessors. Bartholomew Glanville (Bartholomoeus anglicus) about 1350, stated of rabies in his *De Proprietatibus Rerum* that "the biting of the wood hound is deadly and venomous, and *such venom is perilous* for it is long hidden and unknown, and *increaseth and multiplieth itself* . . ." (my italics, vide F. Smith: *The Early History of Veterinary Literature*, vol. i, p. 85, London, 1919).

Fracastorius provides further interest to veterinary historians in his description of the epizootic of cattle in 1514 (Book I, Chapter XII), which is the first recognizable account of foot-and-mouth disease.—I am, etc.,

Department of Pathology, Royal Veterinary College, N.W.1, Dec. 28th, 1930. TOM HARE.

Obituary

Dr. JOHN BASSETT NADEN died on December 16th, 1930, aged 71, after a long and painful illness. He had practised in Warrington and district for thirty-seven years, and was a practitioner most highly respected, both by his colleagues and by the general public. He was born at Hartington in Derbyshire in 1859 (the year, he often recalled, in which Darwin's *Origin of Species* saw the light of publication), and studied medicine at Manchester University. After some experience in practice in various parts of Lancashire, he settled in Warrington in 1893. He established and carried on a successful practice until 1920, when he retired from panel practice. Ill-health compelled him to relinquish a large part of his private practice, but he continued to attend a few old patients until the onset of his fatal illness. He was a good B.M.A. man, and was chairman and secretary of the Warrington Division, and a regular attender at the Divisional meetings. He was appointed charities secretary in 1927, and it was largely due to his zeal in this office that the Warrington Division has figured so well, for a small Division, for its regular contributions to the Association's Charities Fund. Naden had a very modest, retiring temperament, but he had his enthusiasms, and these were of a purely intellectual character. He was one of the oldest members of the Warrington Literary and Philosophical Society, and held the offices of president and secretary. He was also a member of the Warrington Field Club and Scientific Society and of the Warrington Academy, and was for a term president of the former body. He read several papers to these societies on literary and scientific subjects. He was a co-opted member of the Corporation's Museum Committee, and was made a justice of the peace in 1909. As indicated, Naden's tastes were purely intellectual. During the scanty leisure of a busy general practice he managed to read and study most of the English classical authors. Wordsworth and Thomas Hardy were his favourites, and from Hardy he imbibed something of that author's philosophic fatalism. Naden's paper on *The Dynasts* provided a memorable evening in the annals of the Warrington Academy. In his later years he was greatly attracted to the advances and discoveries in atomic physics, and to enable him to understand these better he studied the differential and integral calculus. He became fairly proficient in solving equations, and the pleasure and insight which this knowledge gave him into mathematical physics was both keen and penetrating. Few men outside academic circles understood the theory of Relativity better than he, and he did understand it; he never made any pretence to gain praise for knowledge he did not possess. For many years he attended the Annual Meetings of the British Association, and Section A (Mathematics and Physics) was his favourite Section. A colleague (J. S. M.) writes: Naden was an earnest, sincere, quiet, lovable man, with tastes very alien to a bumptious, boisterous, sport-loving world. He loved his profession, and gave it competent service, but he did not love it so much for what it would bring, rather for what it gave—a gateway to that wider knowledge of man and the universe. His funeral at Hillcliffe Graveyard, on December 19th, was largely attended by his professional brethren, friends, and representatives of the Warrington Corporation.

The Services

HONORARY SURGEONS TO THE KING

Major-General J. D. Graham, C.I.E., I.M.S., and Lieut.-Colonel J. McPherson, I.M.S. (promoted Brevet Colonel) have been appointed honorary surgeons to the King.

OPERATIONS IN THE NUER COUNTRY

The name of Captain Alexander Macdonald Simson, R.A.M.C., lately attached Sudan Defence Force, is included in the list of names brought to notice by the High Commissioner for Egypt and the Sudan for distinguished services rendered in connexion with operations in the Nuer country between December, 1927, and February, 1928.

R.A.M.C. PROMOTION EXAMINATION

The following were successful candidates at the examination of officers with a view to promotion held at home stations in October last:

Majors R. B. Price, D.S.O., A. F. C. Martyn, E. Percival, D.S.O., M.C., F. G. A. Smyth, A. C. Jebb, T. J. L. Thompson, M.C., G. H. Haines, M.C., and G. T. Garraway; Captains W. Y. Eccott and W. B. F. Orr.

DEATHS IN THE SERVICES

Colonel Nicholas Charles Ferguson, late R.A.M.C. (ret.), died at sea on September 20th, aged 68. He was born in Dublin on July 10th, 1862, and was educated at Trinity College, Dublin, graduating as M.B. and Ch.B. in 1884. Entering the Army as surgeon on May 30th, 1885, he became lieutenant-colonel after twenty years' service, and was promoted to colonel in the long war promotion list of March 6th, 1915. He served in the South African campaign of 1896, receiving the medal, and in the South African war throughout, from 1899 to 1902, when he took part in operations in the Transvaal, including the actions at Colesberg, Pretoria, Johannesburg, and Diamond Hill, in the relief of Kimberley, and in operations in the Orange River Colony, including the actions of Paardeberg, Poplar Grove, Dreifontein, Vet River, and Zand River, was mentioned in dispatches in the *London Gazette* of April 16th, 1901, and received the Queen's medal with six clasps, the King's medal with two clasps, and the C.M.G. In the war of 1914-18 he served as D.D.M.S., and was mentioned in dispatches in the *London Gazette* of February 17th and June 22nd, 1915.

Major Alfred Philip Henry Griffiths, R.A.M.C. (ret.), died at Steyning, Sussex, on October 25th, aged 71. He was born at Bideford on June 16th, 1859, was educated at Guy's, and took the M.R.C.S and L.S.A. in 1883. Entering the Army as surgeon on August 1st, 1885, he became surgeon major after twelve years' service, and retired on August 1st, 1905. He was re-employed during the war of 1914-18, from August 8th, 1914.

Universities and Colleges

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

M.D.—(*Branch I, Medicine*): A. J. Amor, G. C. Babington, L. I. M Castleden, W. P. M. Davidson, C. P. Donnison, Margaret R. Dunlop, Doris L. Durie, H. Evans, H. P. Himsworth, A. B Kettle, G. O. Mitchell, M. B. Mody, M M. Posel, L H Savin, A. G. Watkins, Dorothy E. Wright, Elsie B Wright (*Branch IV, Midwifery and Diseases of Women*): Mary C. E. Constantine, Victoria M. Crosse, Helen R Goodman, Beatrice G. Smith, Edith J. L Smith, Jean S. Thomson. (*Branch V, State Medicine*): Amelia M. Ison, E. H R. Smithard.

UNIVERSITY COLLEGE

A public lecture, with lantern illustrations, on "The Peking man," will be given by Professor G. Elliot Smith on Thursday, January 15th, at 5.30 p.m. A course of six public lectures, by Dr. H. R. Ing and Dr. Winifred M. Wright, on physical properties and chemical structure of drugs in relation to pharmacological action, will be held on February 24th and 26th, March 3rd, 5th, 10th, and 12th. Two public lectures on the central nervous system will be given by Professor B. Brouwer, University of Amsterdam, on March 16th and 17th.

A course of ten lectures on comparative physiology will be given at the College, Gower Street, by Mr. G. P. Wells, on Fridays, January 16th, 23rd, 30th, February 6th, 13th, 20th, 27th, and March 6th, 13th, and 20th, at 5 p.m. The lectures are delivered to students of the University and to others interested in the subject; admission is free without ticket. A practical course for a limited number of students will commence on January 21st.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

The following series of lectures in pathology will be given at University College Hospital Medical School on Tuesdays, at 5.15 p.m. January 20th and 27th: Dr. J. A. Murray, induction of cancer by tar and other agents. February 3rd and 10th: Dr. W. Cramer, filterable tumours. February 17th and 24th: Dr. Janet Vaughan, pathology and treatment of pernicious anaemia. March 3rd and 10th: Dr. C. H. Andrewes, immunity in virus diseases. The concluding lectures of the series will be given by Dr. E. W. Hurst, who, on March 17th, will speak on the pathology of poliomyelitis, and on March 24th on disseminated encephalomyelitis following the exanthemata (vaccination, etc.). Admission is free to medical students and graduates.

Medical News

A combined meeting of the Tuberculosis Association and the Section of Obstetrics and Gynaecology of the Royal Society of Medicine will be held at 1, Wimpole Street, W., on Friday, January 16th, at 8 p.m., when a discussion on the management of pregnancy, parturition, and the puerperium in tuberculous women will take place. The openers will be Dr. Geoffrey Marshall and Dr. Melville Hiley on behalf of the Tuberculosis Association, and Mr. Aleck Bourne and Mr. L. Carnac Rivett for the Section of Obstetrics and Gynaecology.

The Hunterian Lecture will be delivered before the Hunterian Society of London at Apothecaries' Hall, Water Lane, E.C., at 9 p.m. on Monday, January 19th, by Dr. Arnold Lorand of Carlsbad on "The problem of rejuvenation." The annual dinner of the society will be held at the May Fair Hotel on Thursday, February 19th.

The Easter course of special public health lectures arranged at the London School of Hygiene and Tropical Medicine will open next week. Dr. W. G. Savage will lecture on bovine tuberculosis on Wednesday, January 14th, at 5 p.m., and Professor J. W. H. Eyre will lecture on January 21st on shellfish and the public health. The series of lectures arranged for the Easter term will end on March 5th, and the summer term will begin on April 28th and conclude on June 26th. The lectures are free to members of the public health service and to others interested in public health work.

The next meeting of the British Institute of Radiology (incorporated with the Röntgen Society) will be held at 32, Welbeck Street, W., on Thursday January 15th, at 8.30 p.m. Papers will be read by Dr. J. F. Brailsford on hydatid disease in England, by Professor E. A. Owen and Mr. H. I. Jones on ionization chambers for *x*-ray dosage measurement, and by Professor Owen and Dr. Philip Wright on physical characteristics of the Scheidt ultra-violet ray tube.

The Galton Lecture, entitled "Warnings from Nature," will be given by Sir J. Arthur Thomson before the Eugenics Society at the Galton Anniversary Dinner on Monday, February 16th, in the Rembrandt Hotel, Thurloe Place, S.W. The offices of the society are at 20, Grosvenor Gardens, S.W.1.

By the courtesy of the Royal College of Physicians the Harvey film will be shown at a meeting of the University of Birmingham Medical Society, to be held on February 11th, at 7.45 p.m., in the New Biology Theatre at the University, Edgbaston, Birmingham. Dr. K. D. Wilkinson, professor of pharmacology in the University, will give a paper on the life and work of Harvey. The society extends a cordial invitation to all members of the Midland Medical Society, and to medical men and women in the Midlands, to attend this meeting.

The Fellowship of Medicine and Post-Graduate Medical Association announces an intensive course in cardiology at the National Hospital for Diseases of the Heart from January 12th to 24th; fee £7 7s. From January 26th to February 7th an all-day course in medicine, surgery, and the specialties will be given at the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham); fee for the course £5 5s., or £3 3s. for either week. Tickets and detailed syllabus of the above courses are issued by the Fellowship, 1, Wimpole Street, W.1. A series of lectures on early diagnosis has been arranged at 11, Chandos Street, W.1, at 4 p.m. The opening lecture will be given on January 19th by Mr. Zachary Cope on the acute abdomen. A programme of clinical demonstrations in medicine and in surgery has also been arranged; the first will be given by Dr. N. H. Hill at the Metropolitan Hospital on January 19th, at 2 p.m. Mr. R. Maingot will demonstrate the injection treatment of haemorrhoids at the Royal Waterloo Hospital on January 20th, at 2.30 p.m. Medical practitioners may attend these lectures and demonstrations without fee or ticket.

A post-graduate course on diseases of the nervous system will be held at the National Hospital, Queen Square, from February 2nd to March 27th. The general course will consist of thirty-two clinical lectures and demonstrations at 3.30 p.m. each week-day except Wednesday and Saturday, teaching in the out-patient department on each week-day except Saturday, and eight pathological lectures and demonstrations on Mondays at 12 noon. The fee for the course will be £6 6s. A course of twelve clinical demonstrations, chiefly on methods of examination of the nervous system, will be given on Tuesdays and Thursdays at 5 p.m.; fee £2 2s. If there are sufficient applicants a course of ten lectures on the anatomy and physiology of the nervous system will be arranged on Wednesdays and Fridays at 12 noon; fee £2 2s. Particulars can be obtained from the secretary of the Medical School, National Hospital, Queen Square, W.C.1.

The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy has arranged a course of lectures on maternity and child welfare for health visitors, nurses, midwives, superintendents of infant welfare centres, etc., at Carnegie House, 117, Piccadilly, on Mondays, at 6.30 p.m., from January 19th to March 23rd. Tickets may be obtained from the secretary, Miss M. E. Richards, 117, Piccadilly, W.1. In conjunction also with the National Society of Day Nurseries a course of advanced lectures on infant care will be given at Carnegie House on Thursdays from January 22nd to March 26th, at 7.30 p.m. Tickets can be obtained from Miss Maddock, secretary, National Society of Day Nurseries, at the same address.

The General Council of King Edward's Hospital Fund for London passed a resolution on January 6th recording its sorrow at the death of the Princess Royal, and its sense of the loss of Her Royal Highness's interest in the work of the fund and the welfare of the hospitals.

A series of monthly clinical demonstrations for registered medical practitioners will be given at the Hospital for Epilepsy and Paralysis, Maida Vale, W.9, by the members of the honorary medical staff, commencing on Thursday, January 22nd, at 3 o'clock, when Dr. Wilfred Harris will demonstrate. Tea will be provided, and it will be a convenience if those intending to be present will send a card to the secretary.

A course of three public lectures on muscular work and fatigue, arranged by the National Institute of Industrial Psychology, under the Heath Clark Bequest, will be delivered by Dr. G. P. Crowden on Wednesdays, January 21st and 28th, and February 4th, at 6 p.m., at the London School of Economics and Political Science, Houghton Street, Aldwych, W.C.2. Admission to these lectures will be free and without ticket.

The eighth British Congress of Obstetrics and Gynaecology will be held in Glasgow on April 22nd, 23rd, and 24th. On the first day the principal subject for discussion is the clinical and pathological features of ovarian tumour (excluding endometrioma). The names of contributors and the titles of their contributions should be sent by February 1st to one of the honorary secretaries, Professor James Hendry, 7, Clairmont Gardens, Glasgow, C.3, or Dr. John Hewitt, 16, Whitehall Street, Glasgow, E.1.

We are informed by Dr. C. A. H. Franklin, honorary secretary of the Lausanne Medical Graduates' Association, that the following candidates have been approved for the M.D. degree by the University of Lausanne during the past year: O. H. Bellerby, J. J. MacCormick, Major C. McIver, I.M.S., T. A. W. Ogg, Miss L. M. Poynder, and E. Obermer.

As announced in our advertisement columns, the Joint Board of Research for Mental Diseases of the University of Birmingham and the City Mental Hospital Committee invite applications for a scholarship in mental diseases of the value of £250 per annum, tenable for one year, but renewable. Applications, endorsed "Research Scholarship," should reach the honorary secretary, The Council House, Birmingham, by January 24th.

The date of the fourth Italian Conference of Thalassotherapy, which was to be held at Trieste next September has been changed to April 24th to 26th.

Dame Mary Scharlieb, of whom an obituary notice appeared in our issue of November 29th, 1930, has left estate valued at £33,050, with net personalty £32,702. She bequeathed her portrait by Hugh Riviere to the London (Royal Free Hospital) School of Medicine for Women.

The second Alexander Pedler Lecture, entitled "Science discipline," which was delivered by Sir David Prain last October in the University of Liverpool, has been published in pamphlet form by the British Science Guild, price 1s. An abstract of the lecture was given in the *British Medical Journal* for November 1st, 1930.

The menace of leprosy in Manchuria is the subject of an article by Dr. J. L. Maxwell in the January issue of the *Leprosy Review*, the quarterly publication of the British Empire Leprosy Relief Association. Until recently Manchuria was almost free from this disease, but it received from China about three million immigrants between 1927 and 1929, and now leprosy has appeared in the southern part of the country to an extent never before known. Since most of the immigrants take up residence much further north it is believed that the disease is even more prevalent in Northern Manchuria. Other articles in this number of the *Leprosy Review* are a report by Dr. E. G. Cochrane on the extent of the disease in East and Central Africa, and the measures taken to cope with it; an account by Dr. E. Muir of the treatment of residual leprosy; a description of antileprosy work in India; and a note on the progress of treatment in the Tanganyika area.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediseera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Nail Biting

"A. V. C." writes, in reply to "M.B.'s" inquiry (p. 42): Far the most efficient method is to use a very fine file (not the ordinary nail file of the dressing-table, but one about 4 inches long and of thin steel). For a child this should be used for each and every nail once a day by a careful nurse. If there are no "tags" left from a previous bite there is no incentive for the child to "pull at something" in states of nervousness. After a month less frequent attention is required, as the habit is largely overcome.

"Warbles" in Man

DR. E. C. SNOW (manager of the United Tanners' Federation) writes: The letter by "F. L. M." on the subject of "warbles" in man has been brought to my attention by Dr. John Gay, the Master of the Leathersellers' Company. The subject of "warbles" in cattle is one of very great importance to the leather industry, and this federation is naturally in possession of a considerable amount of literature on the subject. There are a number of cases recorded in which the larvae of hypodermae (the "warble") have been extracted from man. Most of them have been in children, and usually the affected individuals have been more or less associated with cattle. Accounts of a number of cases on record have been published in a publication issued by the United States Department of Agriculture (Department Bulletin, No. 1369), on page 17. It has now been demonstrated that the beginning of the life-history of the hypodermae, at any rate in cattle, and probably therefore also in the human being, is through the fly laying eggs upon the hair of the legs. In a short time the egg is hatched, and the larvae penetrate the skin. Presumably the boy was infected when the flies were active last summer, and the exit of the maggot in his case has occurred earlier than would have been the case with cattle, the "warble" in cattle not appearing earlier than February, or even later. Judging from the infrequency of "warbles" in man, it is extremely unlikely that this boy would be infected again, but a certain way of avoiding it would be to dress the cattle with which the boy is likely to come into contact at suitable times in the spring and early summer. This dressing, if effectively carried out, will kill the maggots in the cattle, and prevent the development of the fly, and hence the laying of the eggs. Particulars of the dressing are contained in a leaflet (W.F.2) issued by the Leathersellers' Company's Warble Fly Committee.

DR. CHARLES D. FERGUSON (Lochmaddy, North Uist) writes: Let me describe a somewhat similar case to that reported on December 20th, 1930 (p. 1072). A boy, aged 10,

complained of a small raised swelling, itchy and a little painful, situated just below the spine of the right scapula. Examination showed that in the centre of this small ovoid swelling was a circular opening into which a good-sized probe could be passed. On gentle pressure a maggot was expressed It was about half an inch long and three-eighths of an inch broad at its thickest part. Some days later similar swellings appeared over the left mastoid region, and over the great trochanter of the right femur. The patient was healthy, but came in contact daily with cattle, and admitted having squeezed similarly shaped maggots out of the backs of cattle in the spring-time, when the warble maggot is so very common. The life-history of the warble fly is very complex; most entomologists maintain that the ova are deposited in the region of the hoof, but that the young larvae penetrate the skin, and after undergoing various transformations, which occupy about eight to nine months, make their way towards the surface of the body of the host, usually the back. Once infection has occurred, it is doubtful if any form of treatment is useful. When all the maggots escape there is a natural end to the infection.

MR. R J. SCHARFF (Co. Dublin) writes to say that one of the most competent authorities on the life-history of the warble fly is the Rev G. H. Carpenter, D.Sc., Keeper of the Manchester Museum, who has written many papers on the subject.

Accidental Compression of Ureter

"G. P." writes: A surgeon, when operating on a patient for a uterine complaint, put a Spencer Wells forceps on the ureter by mistake. Later the compressed part sloughed, and infiltration of urine into the tissues was the result. As a general practitioner I should like to know how a good surgeon would rectify his error.

Dax-les-Bains

"P. H." asks for information about the types of rheumatism usually sent to Dax-les-Bains, near Biarritz.

*** Dr. F. Parkes Weber, to whom we have referred the query, gives the following list of conditions considered suitable for treatment at this spa: chronic rheumatoid arthritis and osteo-arthritis cases, muscular rheumatism, rheumatic neuralgias, sciatica, and old traumatic joint troubles.

Income Tax

Interest Paid to a Bank

"I. E." borrowed £1,000 from a bank to purchase a share in a practice. Is he entitled to any allowance for the amount of interest paid by him to the bank?

*** Yes. He should obtain a certificate from the bank each year of the amount of interest paid by him and forward it to the inspector of taxes with any receipts, counterfoils, etc., which he may have to show he has paid tax, and he will receive an allowance in respect of the bank interest.

Proportion of House Expenses Chargeable

"Z" runs a practice from his residence, and is allowed to deduct one-half of the rateable value and cost of lighting and heating to cover use of surgery, waiting-room, and garage He has a resident patient for whom he provides the best bedroom, and a second bedroom for the resident nurse. What should be deducted for the cost of that accommodation and of the food, etc., provided?

*** So much depends on the particular circumstances of cases like this that any "rule-of-thumb" method is apt to be misleading. So far as the general expenses—for example, rent or rateable value, lighting and heating, domestic service, etc.—are concerned, probably the best line of approach in this case is to look at the other side of the question—that is, to decide what can fairly be regarded as the proportion to be attributed to the accommodation, etc., of "Z" and his family. If, for instance, it represents one-third, then, as one-half is already allocated to the general practice, the amount still available as an income tax deduction would be one-sixth. So far as food is concerned, the basis might be a proportion—for example, two-sixths if the total number of residents is six—with some subsequent modification for special diet, preferential treatment, etc.

LETTERS, NOTES, ETC.

Natural Healing of Ulcers

DR. NORMAN H. JOY (Reading) writes: I have been much interested in Mr. Dickson Wright's treatment of varicose ulcers, because it is an improvement of a method I thought of years ago. I had regarded the question from one point of view only, which Dr. Silcock, in his letter (January 3rd, p. 34), has completely missed. He wants to know whether the improvement of treatment is due to the injections or the supporting bandages. I consider the chief part of it is due to the ulcer being allowed to heal in a natural way, instead of being constantly interfered with. What chance has the newly formed skin got to spread over the ulcer when it is constantly being interfered with by fomentations, etc.? We have to remember how very delicate this newly formed skin is. I feel certain we are wasting an enormous amount of money and time by using too many fomentations, etc., as a matter of routine, and also many a wound is redressed unnecessarily. I have recently had a case where a man had had the last joint of a finger accidentally cut off. Of course, the stump was suppurating; therefore, of course, it had to be bathed twice a day. When I saw it I at once put on boric lint, and looked at it five days after. The stump was far more healthy, and the skin had started to cover it, and the man told me it was far more comfortable.

Tuberculosis in Labrador

The fourth annual report of the Grenfell Association of Great Britain and Ireland for the year ended September, 1930, refers to the need for more extensive public health work on the coast of Labrador, especially in tuberculosis. At Harrington Harbour last winter seven of the eight patients in the local hospital at one time are stated to have suffered from this disease. The proportion is evidently not abnormal, and is attributed partly to careless habits and unhygienic domestic conditions. Progress in preventive education is hampered by lack of suitable material for propaganda purposes. Other prevalent diseases were pneumonia, rickets, and beri-beri, which were aggravated by the lowered resistance and insufficiency of food and clothing during an exceptionally severe winter. In appealing for increased financial support to maintain its hospitals, nursing stations, and industrial centres, the committee (82, Victoria Street, S.W.1) draws attention to the fact that about £10,000 will be required to rebuild its hospital at Battle, which was recently destroyed by fire.

Natural Labour after Caesarean Section

DR. T. P. ZUM BUSCH (Liestal, Switzerland) writes: The following case may be of interest to your readers in relation to the letter by "H. M." (November 22nd, 1930, p. 891). A woman, over 40 years of age, was brought to the Liestal Hospital one morning at about 8 a.m. in an apparently moribund condition. Sixteen years ago, when in the last weeks of her first pregnancy, she had been stabbed in the abdomen with a large butcher's knife. The stomach and small intestine had been perforated in several places, as well as the uterus and foetus. The latter was removed dead by Caesarean section, and the injuries to the viscera were repaired. In the following years five healthy children were born naturally. She had again been pregnant for nearly nine months, and on getting up on the night before admission to pass water had suddenly been seized with violent abdominal pain. Her condition becoming worse, a medical man was called, who ordered her removal to the hospital, where she arrived about four hours after the onset of pain. I diagnosed rupture of the uterus, and at once opened the abdomen under local anaesthesia, when a nearly fully developed foetus and the placenta were found lying free in the abdominal cavity, which also contained a large quantity of blood; the tear went through the old scar. The well-contracted uterus was removed, and the patient made an uninterrupted recovery.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46, 47, and 48.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 11.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

28 Tuberculosis and Marriage

L. BERNARD (*Le Scalpel*, November 8th, 1930, p. 1290) concludes that the risk of inheritance of tuberculosis is almost negligible; if any bacillary infection occurs through the placenta, it must be very rare. The fact that separation of newborn children from tuberculous parents gives a negative cuti-reaction points in the same direction. Most of the cases of tuberculosis which occur are due to subsequent infection from relatives. Prophylactic vaccination and careful attention to the risks of such infection will do much to prevent the onset of the disease. With regard to conjugal infection, the author states that in such cases the evidence does not point to recent infection, but rather to the activation of an old lesion contracted in infancy. Recent statistics relating to 535,000 tuberculinized families gave a proportion of 10 per cent. conjugal infection. When the infected member in the family shows signs of tuberculosis, it is generally some time after the death of the infecting partner, which shows that the distress of mind or of affairs which often follows plays an important part in the etiology. Since widows are more likely to be affected in this way, secondary tuberculosis is more often met with in them than in widowers. Extrapulmonary tuberculous infections, if cured, are no bar to marriage, with the exception of genital tuberculosis. Bernard discusses different types of pulmonary tuberculosis in relation to marriage, insisting that each case must be considered on its own merits. Marriage is forbidden when the tuberculous process is active, but when it has been arrested the patient may be allowed to marry, though in the case of the woman the additional risk of pregnancy has to be remembered. Fibroid types of localized caseous types of tuberculosis do not seem to be materially affected by the risks of maternity.

29 Spontaneous Tetany in Adults

H. A. SALVESEN (*Acta Med. Scand.*, October 17th, 1930, p. 511) reports three cases of spontaneous tetany in women. In his first patient, an unmarried woman aged 46, the condition appeared to be idiopathic and due to a low blood calcium content. Tetany occurred only in winter and was probably referable to deficient sunlight. Ultra-violet irradiation restored the blood calcium content to the normal and brought about general improvement, the patient gaining 11 lb. in weight. The author's second patient, a married woman aged 25, suffered from tetany and diarrhoea, which were cured by calcium administration. Apparently this was a case of " maternity tetany " brought on by temporary thyroid deficiency. Salvesen's third patient was a married woman, aged 45, who had had several abortions. After prolonged dyspepsia and diarrhoea, she developed a severe attack of tetany, the stools containing 4.5 per cent. of fat. She improved for a time but then died, and the necropsy revealed an atrophic, cirrhotic pancreas. The author suggests that in this case the tetany was not due to hypocalcaemia, but was probably a low chloride tetany in a patient suffering from pancreatic atrophy and consequent fatty diarrhoea.

30 Skin Coloration in Renal Insufficiency

E. BECHER (*Münch. med. Woch.*, November 7th, 1930, p. 1922) has studied the pale yellow coloration of the skin which is often associated with renal insufficiency, especially when there is contracted kidney. The condition contrasts with the skin coloration found in pernicious anaemia, where the whole body is tinted and the serum and urine show abundant colouring matter, in that the appearance of the skin in renal cases is limited to the face and hands and to those parts of the body exposed to the light; the serum is not yellow, and the urine is pale or colourless. Becher finds that in this pale urine, in the serum, and in extracts of the tissues there is a series of chromogens which are transformable into colouring matter by oxidation processes. The excision of both kidneys from an animal is not followed by yellow staining of the serum or tissue extracts. After removal of the entire intestinal tract the urine secreted is pale and free from colouring substance and chromogens, but urochromogen was found in the bowel content. The urochromogen passes by the blood to the kidneys, where it is oxidized into colouring matter, and thence excreted. In the diseased condition of contracted kidney it is probable that there is an impaired oxidizing action on the chromogens which are retained in the tissues and in the blood and carried to the skin. A portion of skin from the back of a patient who had died from contracted kidney was extracted with trichloracetic acid. The extract was colourless at first, but after exposure to light it became yellow; in the same manner the pale urine, after standing in the light, assumed the yellow colour of normal urine. Sunlight converted the colourless chromogen into a coloured substance; in the same way the exposed parts of the body were influenced and became coloured.

Surgery

31 Treatment of Phalangeal Bone Lesions

L. H. MCKIM (*Canadian Med. Assoc. Journ.*, November, 1930, p. 642) considers that only rarely is it absolutely necessary to sacrifice a finger on account of an infective process involving the bone, and emphasizes the importance of treating infections of the fingers conservatively, particularly those with bony involvement. Osseous changes due to infection, and demonstrable by *x* rays, occur earlier in the terminal phalanx of the finger than elsewhere in the body. The presence of a bony lesion, revealed by *x* rays or by an operation, does not necessarily indicate that the formation of a sequestrum will follow. If and when such formation does occur, the loss of even a large portion of a phalanx does not involve amputation of the whole finger. Three cases which illustrate these points are reported. The treatment adopted with success in these patients was incision, removal of a sequestrum if present, and packing the cavity.

32 Post-operative Urinary Incontinence

A. E. GOLDSTEIN and B. S. ABESHOUSE (*Arch. of Surg.*, November, 1930, p. 729) define true or complete incontinence as the complete loss of control of urination and the existence of urinary dribbling at all times, while partial incontinence implies a faulty control of urination, with dribbling between urination on exertion or at the end of urination. It is suggested that one or other form of incontinence exists after prostatectomy more frequently than statistics would show. Incontinence of urine following prostatectomy is less frequent after the suprapubic method than the perineal method of operation, and of 220 cases under review it occurred in only one case out of 134 suprapubic prostatectomies, but in five cases out of 86 treated by the perineal method. Temporary incontinence is a frequent occurrence after either form of prostatectomy, due either to a slight cicatricial contraction in the prostatic urethra or about the vesical neck, in which case instrumental dilatation at frequent intervals will cure the condition, or else to an anaesthesia of the urethra and vesical neck as a result of trauma when the prostate was removed. In this case control is soon re-established if the nerve supply is intact. Bladder exercises after operation help to improve the tone of the vesical sphincters. Permanent incontinence is due to some anatomic or mechanical defect involving both sphincters, and is the post-operative result of manipulation. Urinary incontinence more frequently follows injury to the external than to the

internal sphincter. Injury to the vesical sphincters in perineal prostatectomy may be avoided by retracting the external sphincter and transverse perinei muscles upward; by making the urethrotomy incision for the introduction of the Young prostatic tractor below the external sphincter near the apex of the prostate; by an extra-urethral removal of the hypertrophied gland; and by exerting traction on the prostatic tractor in an upward and outward direction. Methods of treatment for post-operative urinary incontinence range from a plastic operation through the combined suprapubic and perineal routes on both vesical sphincters to the transplantation of a voluntary muscle about the neck of the bladder or urethra. A further paper is promised giving the comparative results of the various methods.

33 Typhoid Phlebitis and Pulmonary Infarction

P. VOIGNIER (*Thèse de Paris*, 1930, No. 307) states that pulmonary embolism is a rare occurrence in the course of typhoid phlebitis. The possibility of its occurrence, however, renders immobilization as necessary as in any other form of phlebitis. Embolism may give rise to sudden or rapid death, and should always be looked for at the necropsy of a typhoid patient who has died suddenly. Pulmonary embolism may also be manifested by haemoptysis. The pathogenesis of infarcts occurring during typhoid fever may be very complicated, but the coexistence of phlebitis and an infarct renders their embolic origin very probable. The prognosis of pulmonary embolism in typhoid fever should be very guarded, owing to the diminished resistance of the patient and especially the involvement of the myocardium. The thesis contains the histories of three cases in patients aged 15, 19, and 36, two of which were fatal, while the third patient only became convalescent after an illness of three months' duration.

Therapeutics

34 Lobar Pneumonia Treated Unsuccessfully with Convalescent Serum

R. T. BEEBE and W. D. SUTCLIFF (*New Eng. Journ. Med.*, October 23rd, 1930, p. 823) have investigated the value of injecting homologous convalescent serum in the treatment of lobar pneumonia. To obtain the best results treatment must be started early, using larger quantities of a serum having a high protective power for mice against the homologous organism. Blood from selected patients was collected four to seven days following the crisis, since protection has been shown to be at its maximum at that time. The donors were those in whom the disease had run a typical course, and in whom the type of organism had been definitely determined. From 300 to 500 c.cm. of blood was collected into a closed flask and allowed to clot at room temperature for six hours. The serum was then placed in an ice-box for twenty-four hours, pipetted off, passed through a Berkefeld filter, pipetted into flasks, and stored in an ice-box. The serum was shown to contain a certain amount of specific protective substance for mice. Two patients with Type II and one with Type III lobar pneumonia were given intravenously amounts varying from 310 to 440 c.cm. within forty-eight hours on the third and fourth days of the disease. One of the Type II patients made a normal recovery after running the usual eight days' course, while the other two became progressively worse and died. Although treated under favourable circumstances, the authors conclude that the results fail to show any benefit from the use of homologous convalescent serum.

35 Treatment of Cardio-vascular Syphilis

J. E. MOORE and J. H. DANGLADE (*American Heart Journal*, October, 1930, p. 148) have studied 90 patients with syphilitic aortic regurgitation, and 43 with aneurysm, in all of whom the ultimate outcome has been traced. While treatment in a few had been adequate for more than a year, in others it had been inadequate, and in some there had been little or no treatment. The nature and intensity of the therapeutic measures employed depended upon the condition in which the patient was first seen. If he was suffering on admission from congestive failure, pronounced pain, or paroxysmal dyspnoea, he was treated in bed by the usual remedies until well compensated. The dangers of therapeutic shock and too rapid resolution of syphilitic inflammatory tissue were guarded against by initial treatment for three months with iodides and bismuth or mercury. A course of twelve neoarsphenamine injections was then given, starting with doses of 0.1 gram and increasing to 0.3 gram. Such courses alternated with courses of bismuth and iodides over a period of at least two years. In patients suffering from aortic aneurysm it was found that while the duration of life in those untreated averaged nine months, this period might be prolonged to an average of nearly six years if treatment for a year or more were undertaken. It was frequently noticed that treatment quickly produced great relief from symptoms, with the result that some patients failed to return for more, thinking they were well. Among the group suffering from aortic incompetence the period of survival after the onset of symptoms in untreated patients averaged two and a half years. If a year or more of adequate treatment had been received the duration of life was extended generally to about five years.

36 Malaria Therapy in Dementia Paralytica

H. R. UNSWORTH (*Journ. Amer. Med. Assoc.*, September 13th, 1930, p. 772) considers that malaria therapy gives the best results in early cases of dementia paralytica, and that little improvement can be expected in patients in the late stages of cerebro-spinal syphilis, when the colloidal gold reduction is very heavy in the first five tubes. The earlier age incidence of dementia paralytica is remarkable. Before the introduction of intravenous arsenical treatment the average age of these patients was over 45 years, and Unsworth attributes this earlier incidence to the promiscuous and unintelligent employment of arsenobenzols. In view of the destructive pathological changes in the cerebral cortex and meninges, it appears hopeless to expect great improvement from chemical therapy, and there is actual danger of causing further destruction. In an analysis of 28 dementia cases inoculated successfully with malaria, Unsworth found that the patients who deteriorated rapidly subsequently were those who had received energetic arsenobenzol treatment. Hence, in selecting patients for malaria therapy, he prefers those who have received little or no arsenobenzol treatment, who are of vigorous physique and otherwise sound organically, and whose colloidal gold reduction is incomplete in the paretic zone. In such patients the response has been satisfactory; some, after three years, are practically normal mentally, while there has been remarkable serological improvement. Those patients who show little or no improvement after malaria treatment are chronic cases with profound colloidal gold changes in the paretic zone, of poor physique, and usually there is visceral disease, especially when energetic arsenical treatment has been given; these patients respond slightly, if at all, to malaria therapy. He has had only two patients who appeared to be immune to malaria, and considers arsenic to be definitely contraindicated in late neurosyphilis.

Anaesthetics

37 Barbitone Derivatives in Intravenous Anaesthesia

J. S. LUNDY (*Anesthesia and Analgesia*, September–October, 1930, p. 210) has employed several drugs of the barbituric acid series in over 2,000 cases at the Mayo Clinic. In 753 cases sodium iso-amyl-ethyl barbiturate (sodium amytal) was given intravenously. In 475 of these cases (63.08 per cent.) a general anaesthetic was administered subsequently. In 23.1 per cent. of these patients, to delirium, was observed oedema occurred in one case, broncho-pneumonia in four, and pulmonary embolism in one. In adult patients the author slowly injects 18 to 30 grains in solution of not over 20 per cent. strength; he has given as much as 45 grains intravenously. Doses of

from 45 to 100 grains are dangerous, although some patients have recovered after much larger doses. The drug produces a rapid drop in the blood pressure, and Lundy discontinues the injection if the systolic pressure falls below 85 mm. Hg. More recently he has used sodium ethyl-1-methyl-butyl barbiturate (sodium embutal) in 403 cases; in 52 of these the drug was injected intravenously, in 15 cases it was given per rectum, and in the remainder orally. Apparently this drug is more powerful; 9 to 15 grains suffice to ensure a similar degree of hypnosis to that obtained from 18 to 30 grains of sodium amytal. Sodium embutal produces less restlessness and delirium. An overdose may cause pulmonary oedema or broncho-pneumonia such as may follow administration of any other barbiturate. Lundy administers sodium embutal in 6.66 per cent. solution. He believes that its sedative effects (by allaying fear) reduce the risks of general anaesthesia. Lundy's conclusions are as follows. (1) The barbiturates should be given in small (hypnotic) doses, on account of their well-known dangers. Their employment for intravenous anaesthesia is unjustifiable. (2) Intravenous administration of tribromethyl-alcohol (avertin) is not so good as the rectal method. (3) Sodium amytal and sodium embutal are preferable to any of the other barbiturates. (4) Sodium amytal is definitely antispasmodic and hypnotic, and should be employed when a prolonged effect is desired. (5) Sodium embutal is antispasmodic and sedative, and is useful in preparing patients for operation, and in cases in which a shorter duration of the effect is desired. (6) Patients are enthusiastic regarding the action of barbiturates. (7) The hypnotic dose of a barbiturate should be given at night before operation, and repeated in the morning, together with a preliminary dose of morphine and atropine.

38 Rectal Narcosis in Ophthalmic Surgery

O. GAYER MORGAN and J. M. LEES (*Brit. Journ. of Ophthalmol.*, November, 1930, p. 577) remark that the choice of anaesthetics for ophthalmic surgery is important and difficult. In some cases local anaesthesia is best, while in others more complete analgesia or anaesthesia is required, with or without the retention of the patient's co-operation. Large doses of morphine associated with a local anaesthetic frequently cause post-operative nausea or vomiting. The mask usually employed in a general anaesthetic is often in the way of the operator, while in old people with chronic bronchitis and emphysema a general anaesthetic, such as is required in septic or inflamed conditions, may set up serious complications. Chloroform, though the most satisfactory anaesthetic, is shunned by anaesthetists, while ether, though safer, produces inconvenient congestion of the tissues. Rectal narcosis with avertin in minimal doses (0.06 gram per kilo) allays fear and renders a certain amount of pain bearable without destroying co-operation on the part of the patient. The administration of larger doses (0.07 to 0.08 gram per kilo), combined with local anaesthesia, takes the place of general anaesthesia, or reduces the amount required. A maximum of 0.09 gram per kilo was used for such procedures as extirpation of the lacrymal sac, plastic operation around the eye, and enucleation. In certain cases chloroform and ether, or intratracheal gas and oxygen, were required. The method of administration followed the instructions in the Bayer handbook. An early morning enema wash-out was followed one hour before operation by the injection of 0.25 grain of morphine with 0.01 grain of atropine; these drugs may be omitted. Half an hour before the operation the calculated amount of avertin was heated to not more than 40°C., and tested by Congo red; a blue colour indicates a decomposition which leads to colitis. It was then administered slowly over a period of five to ten minutes by rectal tube. A return of this dose by the patient precluded any further administration for four hours. The patient was surrounded by screens and the ears plugged by wet cotton-wool. Sleep followed in ten minutes, and full narcosis in twenty-five to thirty minutes, lasting one and a half to two hours. The jaw was kept forward to prevent asphyxia. The patient awoke in two or three hours and fell into a deep and natural sleep again, following which there was complete amnesia for the narcotized period. The authors find that avertin affects the respiratory centre, and the patient often becomes a little cyanosed; an overdose results in death almost inevitably. The blood pressure falls by 25 to 30 mm. Hg, and the amount of venous congestion that takes place may cause difficulty in extirpation of the lacrymal sac. Avertin, if pure, causes no colitis, and may be used in severe toxaemia and sepsis. This drug should not be employed for patients under the age of 16, or in those who have, or have had, nephritis or severe liver disturbances; but it has been used up to the age of 87. The authors have used avertin successfully in 50 cases, including cataract extraction, acute glaucoma, excision, evisceration, acute dacryocystitis, extirpation of the lacrymal sac, and plastic lid operations.

39 Pulmonary Complications of General Anaesthesia

R. T. KNIGHT (*Minnesota Med.*, October, 1930, p. 694) states that pulmonary complications predominate as one of the most important considerations in choosing an anaesthetic; they are the chief cause of post-operative morbidity and mortality. A review is given of 1,015 general anaesthesias at the University hospitals of Minneapolis. Pulmonary complications followed in 30 cases (3 per cent.), with 9 deaths (0.9 per cent.). Six of the complications, including 4 of the deaths, occurred either too late to be referable to the anaesthesia, or as part of a general septicaemia, due to the surgical condition rather than to the induction. Ether administered alone caused about twice as many pulmonary complications as other anaesthetics. When used as a reinforcement to other anaesthetics it gave rise to five times the pulmonary complications in upper abdominal operations, and twice as many in other types of operations. Upper abdominal, as compared with extra-abdominal, operations were followed by pulmonary complications ten times as frequently with ether reinforcement, five times as frequently with ether alone, and four times as often with other anaesthetics. Knight considers that this indicates that ether is a potent factor in pulmonary complications, but that the upper abdomen as an operative field is a still more important consideration. Ethylene causes less pulmonary irritation than any other inhalation anaesthetic; this feature is almost negligible. Knight prefaces his paper with a few remarks on the explosion hazard, with special regard to ethylene; he classes this as a pulmonary complication, since death occurs from explosion within the lungs.

Obstetrics and Gynaecology

40 Eclampsia in a Diabetic

J. S. QUIN and R. H. MICKS (*Irish Journ. Med. Sci.*, November, 1930, p. 612) record a case of eclampsia in a young diabetic primipara. The diabetes had started two years before the pregnancy, and the patient had been managing her own insulin treatment successfully. When pregnancy began she sought advice about her diet and dosage. The pregnancy ran an almost normal course with the exception of a dental abscess which formed about the sixth month. Sugar appeared in the urine, and the insulin dosage was accordingly increased from 17 to 30 units a day. About the eighth month slight oedema developed in the legs; the systolic blood pressure was 150, and the urine was free from albumin. There was no tendency to pathological obesity. One or two weeks before term the patient became toxaemic. Prophylactic treatment on the lines laid down by Tweedy did not prevent fits, which set in shortly before the induction of labour; 15 occurred in eleven hours before the patient was delivered of a dead infant weighing 12 lb. The death is attributed to the unusual difficulty encountered in delivery, and not to the toxaemia. The eclampsia ceased immediately after delivery, and the patient made a rapid and complete recovery from her toxaemic state. A full description of

the treatment adopted is described. No trouble was experienced from ketosis or hypoglycaemia. Owing to the diabetes, glucose was freely administered, and it did not appear to hinder in any way the success of the prophylactic eliminative treatment. Although the view is held that eclampsia can generally be avoided by diabetic measures early in pregnancy, it is noteworthy that this patient had for no less than two years been on a simple, very moderate, and uniform dietary. On resuming normal diet the patient appeared to have acquired an increased tolerance for carbohydrate, being able to take 75 grams a day without glycosuria and with the help of only 5 units of insulin every morning. The authors conclude that the free administration of glucose, combined with moderate insulin dosage, does not interfere with the treatment of eclampsia, and enables a diabetic to withstand a severe eclamptic puerperium without damage to her metabolic functions.

41 The Use of Glandular Extracts in Labour

M. DAVIS (*New England Journ. Med.*, October 16th, 1930, p. 771) gives a complete report in detail of 50 women on whom thymophysin was used to shorten labour. This preparation is a mixture of pituitary and thymus extracts, on the use of which Dr. Nicholas Temisvary of Budapest made a preliminary report at the German Gynaecological Society in 1925; Davis now reports favourably as the result of his own experience of its use. He found it effective and beneficial in every case, there being no untoward maternal or infantile sequels. He states that thymophysin can be given as soon as regular labour is established. The preferable dose is 0.5 c.cm., repeated after a lapse of 45 to 60 minutes. In every case labour was definitely shortened after the administration of thymophysin. Apparently there was no danger of tetanic contraction of the uterus, particularly if two doses of 0.5 c.cm. were given as recommended by Davis. Cases of secondary inertia of the uterus responded well if the patient was not too fatigued. With careful watching it was found useful to allow trial labour in borderline Caesarean cases. Thymophysin was not effective in inducing labour, and hence could be used to distinguish between true and false labour. A complete statement of the progress of labour is given in each of the 50 cases, together with an account of previous labours. After the administration of thymophysin the minimum time of delivery in primiparae with anterior presentations was 40 minutes; with posterior presentations it was 45 minutes; whereas the maximum time otherwise was 6 hours for anterior and 9 hours 45 minutes for posterior positions. The average time of delivery was 2½ hours for anterior positions and 4½ hours for posterior. In multiparae these times were considerably shortened, the average time of delivery for anterior presentations being one hour and for the posterior it was 4 hours 20 minutes.

42 Rupture of Uterus following Caesarean Section

H. A. RIDLER (*Med. Journ. of Australia*, September 27th, 1930, p. 440) records two cases of Caesarean section in which, in a later pregnancy, further sections for uterine rupture were required, resulting in the organ being saved. In the first case, a patient aged 20, a stillborn child was delivered by Caesarean section; fourteen months later a living child was obtained by the same method. Two years afterwards, about three weeks before term, the previous uterine scar ruptured and the intact membranes presented through the wound. A living child was delivered, and the edges of the old uterine wound were trimmed and sutured; recovery was uneventful, the uterus and normal menstruation being retained. The second patient, aged 26, had a Caesarean section performed in her first pregnancy; during labour three years later the uterus ruptured in its lower segment, while the former Caesarean scar remained intact, but was incised to deliver a stillborn child. Recovery followed suture of both the ruptured lower segment and the incision in the old scar, and the uterus was saved. This latter case is cited by Ridler as an example of the fact that rupture of the lower uterine segment can take place during labour while a former Caesarean scar in the upper segment remains intact.

Pathology

43 The Haemic Effects of Quinine and Alkalis in Malaria

T. A. HUGHES and D. L. SHRIVASTAVA (*Indian Journ. Med. Research*, October, 1930, p. 501) have already shown that quinine in antimalarial doses produced blood changes (leucocytosis) indicative of splenic contraction, and that the effect of oral quinine was greatly increased when alkalis were given in quantities sufficient to render the urine alkaline. The results of further experiments carried out on individuals whose spleens were enlarged from chronic malaria, but who showed no signs of active disease, are now recorded. It was found that adrenaline produces a greater splenic contraction when large doses of alkalis are given. Alkalis do not increase splenic contraction following intravenous injections of quinine in antimalarial doses. During the oral administration of quinine and alkalis the leucocyte count promptly rises, but falls to the original level after two to four days, and there is no evidence of cell proliferation. When the spleen is fibrous and indurated, the leucocytic response to both quinine and adrenaline is abolished or greatly diminished. The intravenous injection of quinine in malaria does not appear to possess any advantage over oral administration as regards its ultimate therapeutic action. Discussing the significance of the enlarged malarial spleen, the authors state that splenomegaly in chronic malaria may be due mainly to proliferation of the reticulo-endothelial cells, to fibrosis, or to both. In a further study (ibid., p. 511) on the haemic action of plasmochin in malaria, these investigators found that this drug, given by the mouth for four to six days in daily doses of 0.1 gram, caused no splenic contraction. The most constant changes in the blood were: a fall in the red and total white cells; a temporary rise in the lymphocytes; and a sharp fall in the monocytes when these cells were at or above the upper limit of the normal.

44 Cholesterin Titre of Blood Serum

G. STIRPE (*Il Policlinico*, Sez. Prat., November 10th, 1930, p. 1625) has criticized the views of Chauffard and others that increase in the cholesterin content of the blood serum may be exogenous and referable to diet. To a series of 30 persons, 10 of whom were normal, 10 had raised arterial tension, and 10 had biliary calculi (the last two groups having more or less marked hypercholesterinaemia), was given a fixed diet, to which was added daily an amount of cholesterin varying from 1.5 to 2 grams contained in 4, 6, to 10 eggs. The cholesterin content of the blood serum was determined after four, seven, and ten days of this regime, by Grigaut's method. The author was unable to establish any significant difference between the cholesterin titres of the serum before and after the experiments. The slight changes observed were probably due to errors inseparable from colorimetric determinations.

45 The Germination of Tetanus Spores

B. C. J. G. KNIGHT and P. FILDES (*Biochem. Journ.*, 1930, vol. xxiv, p. 1496) have worked out what is usually described as the "degree of anaerobiosis" necessary for the germination of tetanus spores. The method used was to poise the oxidation-reduction potential of a sample of sterile broth at a constant level by passage of a stream of very dilute oxygen in nitrogen, controlled by simultaneous electrometric observation of the potential. After the potential had remained constant for an hour or two, spores were added to the medium; samples were withdrawn at intervals to ascertain the time at which germination started. Working with a medium of *p*H 7.0 to 7.65, it was found that germination took place readily at an oxidation-reduction potential of Eh 0.00 volt, but that up to Eh + 0.11 volt a limited amount of germination occurred, though the emerging bacilli were often malformed and divided only after considerable delay. Above Eh + 0.11 volt no germination was observed. Germination occurred most rapidly when the Eh was negative to 0.05 volt, the time required being only about four hours; at Eh + 0.10 volt it was about eight to twelve hours.

LEO INSULIN

Marketed under Licence from the Ministry of Health No. 038

CONTAINS NO PRESERVATIVE

100 units per 5 c.c. (each c.c. represents 20 units) - - 1/6
200 units per 5 c.c. (each c.c. represents 40 units) - - 2/10

LEO PHYSEX

(Standardized hypophyseal anterior-lobe hormone)

INDICATIONS

Neurasthenia; Impotence of non-anatomical origin in youth; certain forms of Amenorrhoea and Dysmenorrhoea; Dystrophia adiposogenitalis; Inhibition of growth from hypophyseal disturbance; Pluriglandular Insufficiency.

PACKING—Boxes containing 10 ampoules of 1 c.c., 10 ampoules of 2 c.c.
„ 100 „ 1 c.c., 100 „ 2 c.c.

Sole Concessionaires for British Empire—

For the Treatment of Arthritis and Neuritis

"ARTHRYTIN" Trade Mark

BRAND

Ammonium ortho-iodoxy benzoate

"ARTHRYTIN" possesses an action resembling that of the salicylates, but is much more potent in its effects. It is indicated in all forms of acute arthritis, and has given strikingly successful results in many cases of chronic arthropathy.

Supplied in capsules for oral administration, and powder for intravenous and rectal injection.

Prepared in the Laboratories of
MAY & BAKER, LTD.
BATTERSEA LONDON, S.W.11
Telegrams: Bismuth, London.
Telephone: Battersea 1813 (6 lines)

Clinical trial sample and literature on request.

THE GERMICIDAL ACTION OF DIMOL

INTESTINAL ANTISEPTIC

Extract from Report by independent Bacteriologist appointed by "The Lancet."
(Full Report can be read in "The Lancet," 22nd February, 1930, p. 414.)

1. Determination of the Rideal-Walker coefficient of Dimol using organisms isolated from the faeces. (*See* Table I.)
2. Determination of the degree of dilution of the antiseptic leading to death of organisms in 15 mins. (*See* Table II.)

B. faecalis alkaligenes	30	1:6000
B coli	30	1:5000

3. *Examination for toxicity.* — Single doses up to 0.02 g. (equivalent to 1/3 gr.) per kilogramme body-weight were given to rabbits without producing toxic effects. Such a dose corresponds to grs. 20 for a man weighing 10 stone, five times the dose advocated for therapy. No evidence of absorption as shown by carboluria was obtained. Repeated doses equivalent to two and a half times those recommended in therapy also failed to produce ill-effects when given three times daily over a period of four weeks.

CONCLUSIONS

1. Dimol intestinal antiseptic is found to possess a very high Rideal-Walker coefficient against the commoner organisms infecting the intestine.
2. The antiseptic kills completely these organisms in 15 minutes in dilutions ranging to 1 in 7,000.
3. The preparation shows no evidence of producing toxic effects in animals even when given in very large doses. No carboluria was produced.

Copy of full Report will be sent on application to:—

DIMOL LABORATORIES LTD., 40, LUDGATE HILL, LONDON, E.C.4.

NATURAL APERIENT MINERAL WATER

OF

RUBINAT-LLORACH

(Hydragogue, Purgative, and Cholagogue.)

The official analysis shows in each litre about 1601.321 grains of Anhydrous Salts, of which are Sulp. Soda 1485.368 grains, and Sulp. Magnesia 50.301 grains.

Prescribed in cases of Gall-stones, Liver Disease, and threatened Appendicitis, Constipation associated with Gout, Hepatic Dyspepsia, Gastric Fever, and generally in Abdominal Obstruction.

DOSE.

Wineglassful fasting; can be increased according to temperament. Effect is more rapid if followed by a cup of hot tea.

NO GASTRIC IRRITATION. NO ALTERATION IN DIET REQUIRED.

"A moderately powerful stimulant of the liver, and a powerful stimulant of the intestine."

YOU PRESCRIBE LIGHT ABSORBENT UNDERWEAR WINTER AND SUMMER—YOUR PRESCRIPTION IS

● JAEGER PURE WOOL!

No medical man would ever recommend heavy, stuffy fabrics worn next to the skin as a protection against cold. He knows that anything which fails to allow the impurities in the air round the body to escape—anything which fails to absorb perspiration—is definitely harmful. Some form of light porous texture is essential for combining warmth with health. And it is for that very reason that Jaeger underwear—made of Jaeger pure wool—is so often recommended as the healthiest underwear for all seasons. All Jaeger underwear is replaced if it shrinks. There are Jaeger Agents in every town.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

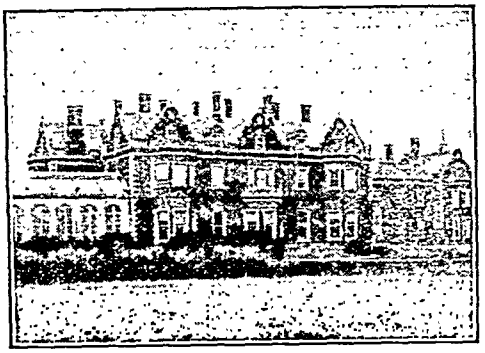
Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.
(Toll Call from London.)



RENDLESHAM HALL.

To those desiring to be near London—

The Mansion, Beckenham Park, Beckenham, as carried on for the last twenty years, is available. Booklet and particulars from the Resident Medical Superintendent.

Telephone: BECKENHAM 1648. *Telegrams:* NOROTORIUM, BECKENHAM.

Proprietors: The Norwood Sanatorium, Limited.

ALCOHOLISM, DRUG HABIT, NEURASTHENIA, etc.

BAY MOUNT, PAIGNTON.

ESTABLISHED 1922. *'Phone:* PAIGNTON 5110.

A comfortable, private HOME, charmingly situated, overlooking Torbay, near Torquay. Main line 3½ hours from Paddington. Both Ladies and Gentlemen admitted as voluntary patients.

The treatment is the outcome of many years' experience, and besides removing all craving for drink or drugs, it has a tonic action on the system and the general health is improved. Alcohol and drugs reduced gradually, without suffering.

FUNCTIONAL NERVOUS DISEASES AND NEURASTHENIA are also treated with excellent results. Cases with insomnia, depression, etc., do especially well.

Exceptionally good climate and ample and varied amusement. Moderate, inclusive terms. Prospectus, etc., from STANFORD PARK, M.B., Ch.B., Res. Med. Supt., Bay Mount, Paignton.

INEBRIETY

ECCLESFIELD, ASHFORD, MIDDLESEX.

(Also private address to secure secrecy.) Telephone: 158.

Beautiful large Residential Home, with 50 acres of park land, attached to R.C. Convent, and under the care of the Sisters. Established 1899. Most successful MEDICAL and PSYCHOLOGICAL TREATMENT for LADIES. Every home comfort, and bright happy social amusements. Splendid results proved by the numbers of former patients who return to the Home for holiday visits. *Medical Superintendent*: J. YOUNG SCOTT, M.B., Ch.B., and J. KENNEDY.

INEBRIETY

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

Dudley Road Hospital.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

[illegible] invited from fully qualified [illegible] appointments as Junior [illegible] (male) at the Dudley Road Hospital, Birmingham.

The Hospital accommodation is fixed at 926 beds, divided into Medical, Surgical, Children's Infectious, Maternity, Gynaecological, and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, Deep Therapy, X-ray, Electrical Massage, Sunlight, and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time for a further period not exceeding six months.

The persons appointed will be required to assist at operations, to administer anaesthetics, and undertake casualty work and such other duties as may be assigned to them by the Medical Superintendent.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

The officer appointed will be required to pay to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

Further particulars of the appointments may be obtained from the Medical Superintendent, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital, Birmingham, to whom applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Thursday, January 22nd.

Applications are invited for the engagement of PART-TIME MEDICAL OFFICER at the Council's Maternity and Child Welfare Centres.

The person to be engaged must be a registered Medical Practitioner who, prior to April 1st, 1930, has held the appointment of Medical Officer of an ante-natal clinic with the approval of the Minister of Health, or who, subsequent to qualification, has had at least three years' experience in the practice of his or her profession, and special experience of practical midwifery and ante-natal work.

The rate of remuneration will be one guinea for each attendance at centres for sessions lasting one hour or less and one and a half guineas for each attendance at sessions lasting more than one hour.

The engagement will, in the first instance, be for a period of three months.

Applications, stating age last birthday, qualifications, and experience, and accompanied by copies of not more than three recent testimonials, must be forwarded in envelopes marked "Medical Officer," so as to reach the undersigned not later than 12 noon on Saturday, January 24th.

Canvassing members or officers of the Council in any manner whatsoever is prohibited and will disqualify candidates. Moreover, the Council do not bind themselves to engage any of the candidates.

Municipal Offices, By Order,
Raine Street, WM. McCARTY,
Old Gravel Lane, E.1. Town Clerk.
December 30th, 1930.

County Council of Durham.

SEAHAM HALL SANATORIUM.

MEDICAL SUPERINTENDENT.

The County Health Committee desire to receive applications for the post of Medical Superintendent of the above Institution, which has accommodation for about 80 female patients, and further accommodation is shortly to be provided by the Council for 50 additional beds.

The salary will be at the rate of £600 per annum, with furnished quarters and board, etc., valued at £150 per annum. In the case of a married man, the emoluments will be paid in cash, as there is accommodation (a cottage) for which a charge of £55 per annum is made by the County Council to cover rent, rates, and water.

The officer appointed must be a registered Medical Practitioner, and must devote whole time to the duties required of such person by the County Council. It is essential that the person appointed shall have held house appointments in a general hospital, and have had practical experience in the administration of a tuberculosis sanatorium and in the treatment of tuberculosis in such an institution, including X-ray and ultra-violet ray treatment, and in bacteriological laboratory work. Such officer must also be specially experienced in the orthopaedic treatment of non-pulmonary tuberculous cases.

The person appointed will be attached to the County Health Department and will be required, subje ontrol of the County to take full respons manage- ment of the ic supervision of the patients.

The appointment will be terminable by three months' notice on either side. A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to the successful candidate passing the County Council's medical examination in connection therewith.

Applications, endorsed "Medical Superintendent, Seaham Hall Sanatorium," with copies of not more than three recent testimonials, must be delivered to the County Medical Officer, Shire Hall, Durham, on or before the 22nd instant.

Shire Hall, HAROLD JEVONS,
Durham. Clerk of the County Council.
January 5th, 1931.

The Royal National Hospital for CONSUMPTION FOR IRELAND, NEWCASTLE, CO. WICKLOW.

The post of JUNIOR RESIDENT MEDICAL OFFICER at the above Hospital will be vacant on March 1st.

Salary £200 per annum, with residence and board.

Must be fully qualified.

Applications, with copies of three recent testimonials, to be sent to the Secretary, 13, South Frederick Street, Dublin, on or before Friday, January 30th.

Papworth Village Settlement, near CAMBRIDGE, for the Treatment of all forms of Tuberculosis. Over 300 Beds (male and female).

Applications are invited for the posts of SECOND ASSISTANT MEDICAL OFFICER, salary at the rate of £400 per annum, and THIRD ASSISTANT MEDICAL OFFICER, salary £200 p.a., with board, lodging, and laundry in each case.

Applicants, who should be male, and single, should send their applications, accompanied by copies of not more than three references, to the Medical Director, Papworth Village Settlement, Cambridge.

Tiverton Hospital, DEVON.

Applications are invited for the post of HOUSE SURGEON. Salary £100 per annum, with board, residence, and laundry. Six months' engagement. Duties to commence as soon as possible.

Application, with testimonials, to be sent to the undersigned.

C. H. DEEKS, Hon. Secretary.

The Royal Eye and Ear Hospital, BRADFORD.

Wanted, JUNIOR HOUSE SURGEON, male. Salary £150, with board, residence, and laundry.

Applications, stating qualifications, age, etc., with copies of recent testimonials, to be forwarded to the undersigned.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place,
Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

IMMUNOGENS

For the Treatment of Catarrh and Pneumonia

IMMUNOGENS are bacterial antigens separated from young cultures of micro-organisms by a process of rapid extraction and centrifugalization which prevents the formation of toxic autolysates.

The advantages of Immunogens are:—
The antigen is in readily-available form
The protein content is extremely low
They are not toxic
The reaction is usually negligible
Doses can be given at daily—or even shorter—intervals
Active immunity is rapidly built up.

CATARRHALIS IMMUNOGEN (Combined) contains ecto-antigens of carefully selected strains of micro-organisms commonly found in catarrhal infections of the respiratory tract, and is especially suitable for treatment of the "common cold".

PNEUMOCOCCUS IMMUNOGEN contains the ecto-antigens of the pneumococci (three types) and is intended for the treatment of pneumonia. Serological studies have shown that Pneumococcus Immunogen produces a high antibody response.

PNEUMOCOCCUS IMMUNOGEN (Combined) contains the ecto-antigens from pneumococci (three types) and streptococci (hæmolytic and non-hæmolytic), and is indicated for the treatment of lobar pneumonia *in which the streptococcus is associated with the pneumococcus.*

Supplied in vials of 10 c.c. with rubber-diaphragm caps. Further particulars of the and other Immunogens will be sent on request

ISSUED [illegible] [REGISTERED AS A NEWSPAPER

ANTIPHLOGISTINE

ANTIPHLOGISTINE

is the first thought of the clinician in the treatment of

PNEUMONIA

Because

1. It Reduces Pain
2. It Combats Toxaemia
3. It Supports Circulation

Applied as a jacket over the entire thoracic wall, Antiphlogistine will do much to promote rest and sleep, which are essential for sustaining the vitality of the patient.

London: 40, Gloucester Place, Portman Square, W.1

HORLICK'S MALTED MILK IN DIGESTIVE DISORDERS.

In diseases and disorders of the gastro-intestinal tract—gastric and duodenal ulceration, acute and chronic gastritis—it is essential that the diet should be bland and soothing. The food should be in a fine state of division, and care must be taken to avoid constituents which may irritate the mucous membrane. HORLICK'S MALTED MILK is constantly being recommended for use in these conditions. Composed of full-cream cows' milk combined with the soluble extracts of malted barley and wheat, it meets the requirements of both doctor and patient, since it contains nothing to cause mechanical irritation, or to excite a secretion of mucus. It is easily prepared and permits meals of small size at frequent intervals to be taken by the patient in an agreeable and palatable form. HORLICK'S is also an excellent vehicle for the addition of other articles such as eggs to the dietary. HORLICK'S MALTED MILK has also been used with marked success in epidemic diarrhoea and dysentery.

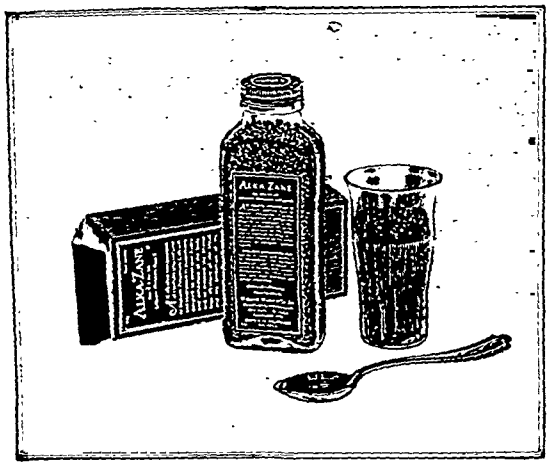
ALKA-ZANE



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

is a palatable and rational antacid, indicated in all conditions of relative hyperacidity, rheumatism, gout, intestinal, gastric, and certain cutaneous disorders.

Prompt in action, lasting in effect, it promotes diuresis, neutralizes excess acid production and helps to rebuild the alkaline bases.

The efficiency of Alka-Zane is demonstrable by the briefest of trials.

A supply for clinical use and literature sent gratis to physicians on request.

BOOTS PRODUCTS
OBTAINABLE THROUGH ALL BRANCHES OF The Boots Chemists

Insulin (BOOTS)

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd., under Licence No 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.
It is made from selected ox pancreas which is subject to the strictest examination before use.
The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out. Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility — these tests being carried out both before and after filling into ampoules.
A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

When children have *coryza* watch the middle ear

MOST cases of otitis media in children result from extension of a common cold or the coryza associated with influenza or the exanthemata. Unless the primary inflammation in the rhinopharynx is treated vigorously, there is always the danger that the infection may travel through the Eustachian tube and into the middle ear cavity.

Pediatrists and otologists alike urge the necessity of watching the middle ear in all cases of coryza in children. By advising frequent nasal instillations of a light oily solution containing menthol, eucalyptol, camphor and chlorbutol—Mistol—it is believed that many cases of otitis media can be prevented or even checked in their beginning.

The use of Mistol is effective treatment for all conditions of nasal congestion. Its anticongestive and stimulating ingredients are contained in a light oil possessing the most favourable properties for spreading on and clinging to the nasal mucosa, so that the preparation reaches every part and is not readily washed away by accumulated secretions.

Mistol assures greater comfort for little coryza patients and also protection for their ears. It may be diluted one-half with Nujol, for infants, and proportionately for children.

Mistol

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational claims but by the constant recommendation of Medical Practitioners.

Benger's Food is scientifically prepared to adjust fresh cows' milk, diluted or undiluted, to suit the individual requirement of the patient. In this respect it is distinct from any other food obtainable.

Benger's Food is largely used as a routine treatment in all cases of impaired digestion. The following comments, recently made by Doctors, indicate some specific conditions in which the Medical Profession prescribes Benger's Food.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

BENGER'S FOOD, LTD., Otter Works, MANCHESTER.
NEW YORK (U.S.A.): 41, Maiden Lane. SYDNEY (N.S.W.): 350, George St. CAPE TOWN (S.A.): P.O. Box 573

Benger's Food, in sealed tins, is on sale throughout the world by Chemists, etc.

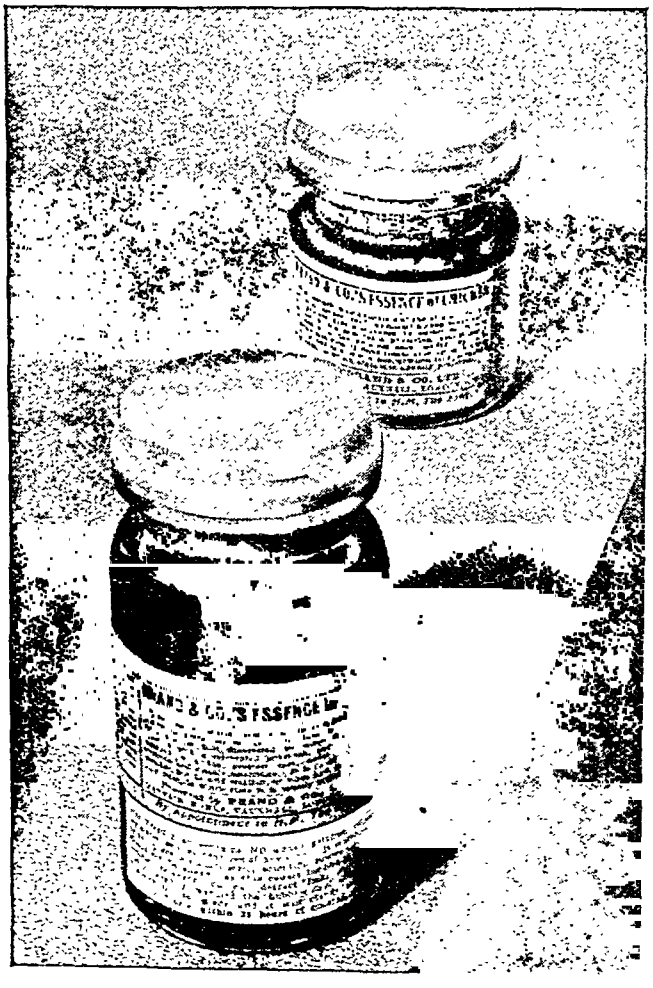
Scientific tests prove

THAT THESE ESSENCES REDUCE THE PERIOD OF DIGESTION BY FORTY MINUTES



No elements harmful to the system—colouring matter, preservatives, or gelatine—are present in Brand's Essences to hinder assimilation. They consist only of the pure essence of meat, drained out under the most hygienic conditions, in its natural form—a clear, appetizing jelly.

RECENT scientific tests have shown that meat essences are entirely assimilated by the digestive organs in one hour and thirty-eight minutes—forty minutes sooner than the normal time taken for digestion.

So high is the flow of gastric juice promoted that it reaches 87% of the total acidity content of the stomach in 37½ minutes.

The absorption thus induced by the powerful stimulation of the gastric secretions is rapid and effortless—leaving no solid residue and making no demands on the digestive system. At the same time the nourishment required to renew exhausted energy is supplied.

For this reason 99 out of every 100 doctors recently interviewed are recommending Brand's Essences of Beef and Chicken in severe illness when the patient is unable to assimilate solid food—or in convalescence, when the appetite needs stimulus.

Brand's Essences of Beef and Chicken are hygienically prepared from the finest, freshly-killed English meats by an exclusive process which conserves the pure strength of the meats without the addition of any preservatives.

They are deliciously palatable and easy to swallow; in cases of cancer, gastro-enteric catarrh and bowel trouble they are an unequalled standby. Samples will be sent on receipt of a professional card. Dept. F.20, Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

A Lecture
ON
ZOSTER, VARICELLA, AND ENCEPHALITIS*

BY
W. RUSSELL BRAIN, D.M., M.R.C.P.
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE; ASSISTANT PHYSICIAN TO THE ROYAL LONDON OPHTHALMIC HOSPITAL

Herpes zoster is now regarded as due to an infection with a virus which is quite distinct from that responsible for herpes febrilis. It is confusing to apply the term herpes to both, and it would be advantageous to confine this term to herpes febrilis and to speak of herpes zoster simply as zoster, on the analogy of the French "zona." The infective character of zoster is an inference from the following facts. The eruption is often preceded by a disturbance of the general health, and sometimes by fever, and causes enlargement of neighbouring lymph nodes. There is a seasonal incidence, most cases occurring in the early summer and late autumn. Small epidemics have been described, and the contagiousness of the condition is well established. There is also a relationship between zoster and varicella, which I shall discuss further below. A patient suffering from zoster may infect others with varicella. More rarely the opposite occurs. Immunity almost always follows the attack, and the histological changes in the skin and nervous system are inflammatory in character. In spite of the strong presumption that zoster is an infection, it is doubtful whether it has ever been transmitted to animals. Lipschütz[13 16] and Grüter's[7] experiments are not conclusive. Kundratitz[11] and others, however, appear to have transmitted it to children by direct cutaneous inoculation. The histological changes in the nervous system in zoster are now familiar. They were first described in 1861 by von Barensprung, and have since been studied by many observers, especially by Head and Campbell[8] and by Wohlwill.[21] In the acute stage there are haemorrhages, infiltration with mononuclear and occasional polymorphonuclear leucocytes, especially in the form of perivascular cuffs, and degenerative changes in the nerve cells. Fibrosis and secondary degeneration follow in severe cases. The changes occur in the first sensory neurone. The posterior root ganglion and its cranial equivalent, the Gasserian ganglion, are most frequently affected, but the spinal cord often exhibits a lesion at the base of the posterior horn, and the peripheral nerves may also suffer. These tissue reactions are clearly inflammatory, and led Head and Campbell, in 1900, to speak of zoster as "an acute specific disease of the nervous system" manifesting itself as "an acute posterior poliomyelitis."

"Symptomatic" and "Idiopathic" Zoster

It is very important for clinical purposes to distinguish two groups of cases of zoster—those with and those without a discoverable predisposing cause. The former are often called "symptomatic" as distinguished from "idiopathic" zoster. "Symptomatic" zoster may occur in the course of intoxications—for example, with arsenic, bismuth, carbon monoxide, and other poisons. Jonathan Hutchinson, in 1868, described cases of zoster arising during treatment with arsenic. It may also complicate infections such as pneumonia or tuberculosis, but is especially liable to occur when the first sensory neurone is itself damaged. Thus syphilitic radiculitis and spinal compression following carcinomatous deposits in the vertebrae are well-recognized causes. In the idiopathic group no obvious predisposing event can be found. Clinical distinctions, however important to the physician, are sometimes biologically misleading, and we now know that "symptomatic" and "idiopathic" zoster are fundamentally identical. Head and Campbell observed thirty years ago that the histological changes of both were indistinguishable. Their etiological identity has been established by Netter[19] by means of complement-fixation tests, which I shall describe later. What, then, is the relationship between zoster and a lesion of the first sensory neurone? This is most direct when a gross injury of the posterior root is followed by zoster. In such a case it is a legitimate inference that the primary lesion has lowered the resistance of the root ganglion to the zoster virus. Known exogenous or endogenous toxins presumably operate in the same way, and it is surely no unjustifiable leap to the conclusion that in idiopathic zoster an unknown factor, infective or toxic, may exercise the same predisposing effect, lowering what Levaditi[14] calls the "tonus immuno-trophique" of the ectodermal tissues of the metamere. Once the virus has invaded the sensory neurone it proceeds peripherally towards the skin and centrally towards the neuraxis. Kundratitz has demonstrated the virus in the vesicles, hence the cutaneous lesions are a zoster dermatitis, and not, as was formerly supposed, "trophic" or primarily vasoparalytic in nature.

Some Clinical Aspects of Zoster

Besides the characteristics of zoster in its commonest form with a cutaneous eruption and sensory disturbance, there are manifestations of the infection which are interesting and important on account of the implication of other tissues. These are not very rare, and may be puzzling if one is not familiar with them.

1. *Ophthalmic Zoster.*—As we have seen, zoster may invade the Gasserian ganglion, in which case the eruption appears in some part of the trigeminal distribution. Usually only a part of the ganglion is involved; hence the eruption is usually confined to the distribution of one division of the nerve. Since the cornea receives its sensory supply from the ophthalmic division, it may be the site of the eruption when this division is attacked. Even so, it may escape, and, as Jonathan Hutchinson first pointed out, it usually does so unless the naso-ciliary branch is involved. Hence the absence of an eruption on the nose in zoster of the first division of the trigeminal usually means that the cornea will escape. According to Paton,[21] in his excellent account of "The trigeminal and its ocular lesions," "the most frequent primary corneal lesion takes the form of small, round infiltrations in the more superficial layers of the substantia propria of the cornea." I must refer you to Paton's paper for the corneal complications of zoster, which are sometimes severe, and may even involve loss of the eye. Other orbital structures may be involved in the inflammation, and the most important complication, fortunately a rare one, is optic neuritis, followed by atrophy and leading to blindness. Oculomotor paralyses sometimes occur, the third nerve being more often affected than the fourth and sixth. Trigeminal zoster, like zoster elsewhere, may be either "idiopathic" or "symptomatic." In the latter case it may follow any intracranial lesion of the fifth nerve, even alcoholic injection of the Gasserian ganglion. It must be distinguished from neuro-paralytic keratitis, a much commoner complication of this therapeutic measure, and from simple herpes of the cornea, which usually manifests itself as a dendritic ulcer.

2. *Geniculate Zoster.*—Zoster of the geniculate ganglion is interesting, not only anatomically, but also as a cause of facial paralysis. This tiny ganglion is the sensory ganglion of the facial nerve, corresponding to the Gasserian

* Delivered to the Glasgow University Medico-Chirurgical Society.

ganglion of the trigeminal and to the spinal posterior root ganglia. Its main sensory function is the reception of taste impulses from the anterior two-thirds of the tongue by the chorda tympani, but it also sends sensory fibres to a variable area of the external auditory meatus and concha, and to the anterior pillar of the fauces and soft palate. Geniculate zoster is associated with typical zoster vesicles in the auricle, less often on the fauces, and with pain in the ear and mastoid region, radiating to the anterior pillar of the fauces and to the vertex. The principal sensory loss in geniculate zoster is of taste in the anterior two-thirds of the tongue on the same side. Its most important clinical feature, however, is facial paralysis, which is almost invariably present (Ramsay Hunt[10]). Since the herpetic vesicles may be inconspicuous, the true cause of the paralysis is likely to be missed by anyone unfamiliar with the condition. The facial paralysis which may be associated with clonic facial spasm is doubtless due to the spread of inflammation from the geniculate ganglion to the facial nerve. Sometimes the eighth nerve is also involved, with resulting deafness or vestibular disturbances.

3. *Lower Motor Neurone Lesions in Zoster.*—We have just dealt with one example of a lower motor neurone lesion in zoster due to involvement of the facial nerve. Occasionally we meet with similar lesions corresponding to the muscular supply of spinal segments. Thus I have seen weakness and wasting of all the muscles supplied by the fifth cervical segment on one side associated with zoster of the same cutaneous distribution. Segmental paralysis of the abdominal wall is fairly common, and similar motor lesions may occur in other situations. It is more likely that they are due to a spread of the inflammation from the posterior to the anterior horns than to mutual involvement of the corresponding roots.

4. *Zoster Arthritis.*—Acute inflammation of the joints is a rare manifestation of zoster which has been little recognized in this country. Six cases have been reported in France, and I have seen two, one a patient of my colleague Dr. Anthony Feiling. In all eight cases the joints involved have been those of the fingers, and in one instance the wrist also. In some cases only one or two fingers have been involved, the joint changes corresponding to the segmental distribution of the eruption. In other cases, including my own patient, all the fingers of one hand were affected, though the eruption was limited to one root segment. In all the reported cases the onset of the arthritis has approximately coincided with the outbreak of the eruption. Pain and oedema have been severe, and in some instances oedema of the skin and subcutaneous tissues has persisted for months. Zoster arthritis seems always to be followed by great limitation of movement of the affected joints, probably due mainly to periarticular changes, since radiograms show few bony alterations, except rarefaction. French writers usually describe these disturbances as arthropathies, but the evidence points to their being, in fact, an arthritis. During the acute stage the clinical appearances are indistinguishable from an acute arthritis, and neither clinically nor radiologically does the condition resemble the familiar arthropathies. As we have seen, there is evidence that the zoster virus spreads along the nerves to the skin, and Paton believes that it reaches the cornea in a similar manner. It is not unreasonable to suppose that sometimes it may reach the joints also.

5. *Zoster Meningitis and Encephalitis.*—If, as there is reason to believe, zoster is primarily a posterior poliomyelitis or ganglionitis, it is not surprising that the infection should sometimes spread to other parts of the nervous system. That the meninges are often secondarily involved is indicated by the frequent occurrence of lymphocytosis and raised protein content in the cerebro-spinal fluid. Chauffard and Froin[3] first drew attention to this, and Chauffard and Rendu[4] described it as "Méningite zonateuse." They pointed out that the evidence for meningitis might be not only cytological, but also clinical, and that cervical rigidity and Kernig's sign might be present. In some cases we find zoster associated not only with meningitis, but with evidence of involvement of the substance of the brain—that is, encephalitis. These cases are not easy to interpret, since we know that symptomatic zoster may follow a lesion of the nervous system, and the question arises whether the zoster is secondary to an encephalitis of different origin, or whether the encephalitis has been produced by the zoster virus. Schiff and Brain[23] have recently reviewed the reported cases of this association and published a further example. They reached the conclusion that although in some instances the zoster was a complication of an independent encephalitis, there remained a group of cases in which an extension of the zoster infection had produced the clinical picture of encephalitis. In their own case this conclusion was supported by complement-fixation tests on the cerebro-spinal fluid, which were carried out by Bedson and Bland,[1] and which afforded evidence of the presence of the zoster virus therein. In the mildest cases, therefore, extension of the zoster infection to the meninges is indicated only by the appearance of inflammatory changes in the cerebro-spinal fluid. In more severe cases the clinical manifestations of meningitis are added, and a further extension may involve the substance of the neuraxis. In zoster meningo-myelitis myoclonus is not uncommon. At least two fatal cases of zoster meningo-encephalitis have been reported.

THE RELATIONSHIP BETWEEN ZOSTER AND VARICELLA

The existence of an association between zoster and varicella appears to have been first observed by Bokay[2] in 1888, and has since been very thoroughly investigated by clinical, bacteriological, and serological methods.

Clinical Observations

1. In Bokay's original instance zoster in one individual was followed after ten days by varicella in a contact. This is by far the most frequent sequence, and has now been recorded hundreds of times. Netter[19] in 1928 had collected 174 examples published in France alone. The same author has investigated the incubation period in 102 cases and found that it ranged from seven to twenty-four days, but more than half of the cases of varicella occurred between the thirteenth and the sixteenth day after exposure. Varicella may thus follow not only so-called idiopathic zoster, but also zoster occurring in the course of arsenical treatment.[19]

2. Conversely, zoster may occur in an individual who has been in contact with varicella, though this is much less frequent. Netter has collected twenty-five cases in which the incubation periods were the same as in the preceding group. The sequence zoster-varicella is eight or ten times as frequent as the sequence varicella-zoster. Hill,[9] recording epidemics of both in an institution, found nine of the former and one of the latter.

3. It is common enough for varicella to breed true and cause varicella in contacts. The same may occur with zoster.

4. All possible combinations of these associations have been recorded. Thus a case of zoster may be followed by zoster in one contact and varicella in others, and the same is true of varicella. In the case of either disorder the first generation of contacts may show the similar and the second the dissimilar illness, or vice versa.

5. The same individual may show both zoster and a scattered eruption resembling varicella. There may be only a few "aberrant vesicles" or a widespread vesicular eruption. The latter has been described by some authors as "zoster generalisatus." Others, struck with its resemblance to varicella, have written of "zoster and varicella in the same patient." Usually the generalized rash appears within three or four days of the outbreak of zoster, but the interval may be longer. Bokay[2] has investigated this point in twenty-nine recorded cases. He found that in ten cases both local and general eruptions appeared on the same day, and in twenty-one the latter was evident before the fifth day. It is sometimes, however, delayed even until the third week.

Epidemiology

Allusion has already been made to the occurrence of epidemics of zoster. Bokay has sought to discover whether these have any relation to varicella epidemics. He therefore obtained such data as were available concerning the incidence of the two disorders month by month in Budapest for the ten years 1915-24. These data are admittedly not complete, and are indices rather than totals. Nevertheless, there is a striking correspondence between the variations in the monthly prevalence of the two diseases. In nine out of the ten years there is an autumn peak, usually reaching its maximum for varicella in November, and in most years a smaller peak in June. A point of interest and importance to which Bokay does not draw attention is that the peak of the zoster curve usually occurs one month before that of varicella.

Bacteriology

Kundratitz[11] was the first worker to claim to have transmitted zoster by inoculation to children. In 1927 he reported twenty-six successful inoculations of children with the contents of zoster vesicles. The usual result was an eruption at the site of inoculation, but a few patients also exhibited a generalized vesicular rash. Children who came in contact with those successfully inoculated developed varicella. Kundratitz previously reported fourteen successful inoculations in twenty-two attempts. The inoculation period varied from nine to fourteen days. Only children who had not previously had zoster or varicella were found to be susceptible. A successful inoculation protected against a subsequent zoster inoculation and also against varicella. Netter[13] quotes eight other workers, and Cleveland[3] one, who obtained similar successful inoculations of zoster, often with transmission of varicella to contacts. It is uncertain whether the serum of patients who have recovered from zoster protects others against varicella. Kundratitz claims positive results. Sicard and Paraf[23] have failed to verify them. Netter, however, justly points out that negative results are not very strong evidence against the common nature of zoster and varicella, since several workers have found that serum from varicella convalescents fails to protect against varicella.

Complement-Fixation Tests

In 1923 de Lange[12] claimed to have demonstrated antibodies to varicella in the blood of a patient suffering from zoster. Netter and Urbain[20] thereupon set themselves to investigate this point by means of complement-fixation tests in a large series of patients. In 1926 they published the results in 100 cases of zoster, of which 84 had had no apparent contact with varicella. In 93 out of the 100 cases deviation of complement occurred when the contents of vesicles either from varicella or from zoster were used as antigens against the blood serum of the zoster patients. Exactly the same results were obtained with the same antigens and the blood serum of patients convalescent from varicella. Netter and Urbain have similarly demonstrated the presence of antibodies to varicella in the blood serum of nine patients in whom zoster followed arsenical treatment, of three in whom it was induced by injections of bismuth, and of two in whom mercury was apparently a precipitating factor. Lauda and Silberstein[18] have failed to confirm Netter and Urbain's complement-fixation tests, but Bokay attributes their failure to a variation in technique. Netter quotes Pincherle and Vegni[19] as having confirmed his findings.

Relation between Zoster and Varicella

What conclusion can we draw concerning the relation between zoster and varicella? It seems incontestable that some cases of zoster are due to a virus which may also produce in contacts a condition indistinguishable from varicella. It is not yet proved, however, that all cases of zoster and all cases of varicella are due to the same organism, though there is evidence which suggests that they may be. The indications that zoster arising in the course of treatment with arsenic, bismuth, and mercury may be of varicellar origin goes far to support the view that lesions of the first sensory neurone also operate only as predisposing causes. If so, the heterogeneous causation of zoster is not an argument against its being due to a single virus. Reports of varicella in contacts with zoster arising secondary to gross lesions of the posterior roots are lacking, and would be very valuable. Netter and Urbain's complement-fixation tests and Bokay's epidemiological investigation go far to link together at least a large proportion of cases of both zoster and varicella.

Let us leave open the question of how far we can generalize, and turn to the interesting problems which arise from the conclusion that at least some cases of both diseases are due to the same organism. Why do some infected persons develop zoster, others varicella, and some both? And why is it about ten times more common for zoster to give rise to varicella than vice versa? Answers to these questions must be largely speculative. Nevertheless, there are some indications as to the directions in which the explanations should be sought. There is a striking difference in the average age of the zoster-from-varicella and the varicella-from-zoster patients. In Netter's first group only eight out of twenty-five were children. The ages of the adults are not all given, but the average of five was 55, and among the remainder were a grandmother, a concierge, and two doctors. On the other hand, almost all the varicella-from-zoster patients are children, the average age of fifty cases reported by Netter being 6 years. These facts suggest that adults are relatively immune to the varicella virus, that immunity wanes as life goes on, and that the adult who becomes susceptible develops zoster rather than varicella. It is tempting to suppose that this hypothetical immunity is due to an early attack of varicella. The special susceptibility of the first sensory neurone in adults may be due to its possessing a tissue immunity feebler than that of other parts of the body, or to its immunity being temporarily diminished by a preceding lesion. Once the infection has established itself in the metamere it may disseminate itself in the blood stream, causing the generalized rash as in generalized vaccinia. From what we know of the effects of partial immunity upon the manifestations of an infection we may hazard a guess that the length of the interval between the outbreak of zoster and the occurrence of a generalized rash is an index of the degree of existing immunity to the virus. The shorter the interval the greater, probably, is the immunity.

Cranston Low[17] has suggested that varicella is a haematogenous infection, while in zoster the virus reaches the posterior root from the cerebro-spinal fluid, to which it gains access from the nose. This may be true, but the significant difference in age incidence seems to require an explanation in terms of immunity.

VARICELLAR ENCEPHALITIS

Much attention has recently been directed to the occurrence of encephalitis as a complication of the acute specific "fevers," and a brief study of varicellar encephalitis and myelitis may prove not only interesting in itself but illuminative of the general relationship between "fevers" and their neural complications. I have been able to find in the literature thirty-two cases which can reasonably be included under this heading. Apart from two patients aged 32 and 23, all were children, the average age in twenty-seven cases being 4½ years. Symptoms of involvement of the nervous system developed as a rule between the fifth and the twentieth day after the appearance of the rash, in most cases during the second week, usually between the seventh and tenth days. The onset was acute, and was generally associated with fever, headache, vomiting, and giddiness, and sometimes with delirium. In the following table I have arranged the thirty-two cases in groups according to their predominant symptoms.

Meningeal	2 cases
Ataxic and "cerebellar"	11 ,,
Tremor	3 ,,
Chorea and choreo-athetosis...	2 ,,
Diplegia	1 ,,
Hemiplegia	1 ,,
Ophthalmoplegia	2 ,,
Spinal	8 ,,
Coma	1 ,,
(?) Polyneuritis	1 ,,

The distinction of "types" in dealing with so diffuse a process as encephalitis is of course artificial. Thus a pyramidal lesion may coexist with ataxia and meningeal symptoms with transverse myelitis. Nevertheless the classification is valuable as indicating the predilections of the disease for certain parts of the nervous system. It is striking that in half the cases disturbances of co-ordination with or without involuntary movements were the conspicuous feature. The ataxia was often so gross that the child was quite unable to walk. The spinal lesion usually produced the picture of a transverse myelitis at the dorsal level of the cord. In one case one upper and both lower limbs were paralysed. It is doubtful whether the diagnosis of "polyneuritis" is correct, since the patient thus diagnosed was not examined till five years after the onset, and was then found to have muscular wasting of all four limbs. In only a small number of cases is there a report on the cerebro-spinal fluid. In some this was normal; in others there was an excess of cells, up to 71 per c.mm. In one case these were polymorphonuclear; in the others their nature is not described, and it may perhaps be assumed that they were mononuclear. The prognosis is good both as to life and as to recovery of function. Of thirty-two patients, only two died—the two adults—one of ascending myelitis, the other in coma twenty-four hours after the onset of the nervous manifestations and on the third day of varicella. As this patient was pregnant, it is possible that the cause of death was related to the pregnancy rather than to the varicella. Only three of the remaining thirty cases appear to have failed to recover completely; even the grossest ataxia usually disappeared within a few weeks. In neither of the fatal cases was there a post-mortem examination, and I have been unable to find any record of a pathological examination in varicellar encephalitis.

Two views prevail as to the nature of post-vaccinal encephalitis: that it is due to the virus of vaccinia, and that it is produced by some other virus which invades the nervous system secondarily to vaccination. The same alternatives have been put forward to account for measles encephalitis, and it has been suggested, chiefly on pathological grounds, that both measles encephalitis and post-vaccinal encephalitis may result from the same secondary invader. Are we to regard varicellar encephalitis as due to the organism of varicella or to this hypothetical neurotropic virus? In this case we have no pathological findings to guide, or perhaps to mislead, us, and we must therefore turn for light to the clinical features. It is instructive to compare certain of the clinical characteristics of encephalitis complicating vaccination, measles, and chicken-pox, tabulated below:

	Post-vaccinal Encephalitis	Measles Encephalitis (Ford[6])	Varicellar Encephalitis
Cerebellar syndromes:			
Frequency	Rare	14 out of 125	11 out of 32
Recovery from	—	12 out of 14 incomplete 10%	All complete
Mortality (all cases) ...	58%*		6%
Recovery of function (all cases)	Good	25% complete 65% incomplete	84% complete 9% incomplete

* English epidemic, 1922-23.

We have here indications that the clinical pictures, mortality rates, and prognosis as to functional recovery are quite different in the three conditions. Those who regard them as due to the same virus will have to suppose that the action of this hypothetical organism is hypothetically modified by the influence of the different pre-existing infections. This may be true, but it seems less speculative to suppose that the differences are due to the encephalitis being produced by different organisms—namely, the viruses of vaccinia, measles, and chicken-pox. The solution of this problem, however, awaits a greater knowledge of these viruses and the discovery of better methods of detecting both the organisms themselves and the antibodies which they evoke in their hosts.

TREATMENT OF PERNICIOUS ANAEMIA WITH HOG'S STOMACH

REPORT OF 108 CASES*

BY

JOHN F. WILKINSON, M.B., M.Sc., PH.D., F.I.C.

DIRECTOR OF THE LABORATORY FOR CLINICAL INVESTIGATIONS AND RESEARCH, MANCHESTER ROYAL INFIRMARY

The successful results of some experiments upon the value of hog's stomach tissues in the treatment of pernicious anaemia were published in a preliminary report upon nine cases so treated in the laboratory.[1] It was found that very good results could be obtained either with uncooked fresh hog's stomach tissues or desiccated preparations of the same. By using such active products in cases of pernicious anaemia remissions were initiated more quickly and progress was better maintained than with the liver treatment. Subjective symptoms, such as glossitis, paraesthesiae, and gastro-intestinal disturbances, were much more rapidly and satisfactorily relieved without the aid of the mixture of hydrochloric acid and pepsin so often necessary in liver therapy. In 1929 Sturgis, Isaacs, and Sharp,[2] working independently along similar lines, reported remission in three cases, using a desiccated preparation. More recently they have made observations upon thirty-nine cases of pernicious anaemia for periods up to ten weeks.[3] These results have been confirmed by workers in other countries, but the number of cases reported has been few, while the periods of observation have not been sufficiently long to indicate the real value of this form of therapy. Conner[4] has reported six cases and Rosenow[5] two where similar treatment was employed for pernicious anaemia. Meulengracht and Hecht-Johansen[6] obtained satisfactory responses using desiccated preparations, but failed to get an active extract (one case) according to Cohn's method with liver. Ungley[7] also failed to produce remissions in two cases treated with fresh sheep's stomach. I have confirmed this result using the desiccated preparation. Five cases have been recorded by Snapper and Dupreez[8] as having been successfully treated with hog's stomach, while Hitzenberger,[9] Faber,[10] Winge,[11] and Lambin and Steenhoudt[12] have also obtained satisfactory results in a smaller number of cases.

GENERAL DESCRIPTION OF EXTENDED SERIES

During the last eighteen months I have extended considerably my own series. Since most of the patients on whom the treatment was first tried have continued to take it, its ultimate value can be estimated more exactly over these longer periods.

The present communication deals with a series of 108 consecutive cases of uncomplicated pernicious anaemia treated at the Manchester Royal Infirmary with preparations of hog's stomach. All these cases were typical for this condition, having reduced red cell counts and haemoglobin values, high colour indices, megalocytosis, achylia gastrica, etc.; a few of them had a less pronounced early postero-lateral involvement of the spinal cord.

For convenience of discussion and comparison the series is divided into three groups, although the cases constitute one consecutive series.

Group I consists of 52 cases, none of which had ever had liver or other special treatment for the condition prior to coming under observation.

Group II consists of 31 cases that had been given liver treatment at some time previously but had relapsed.

Group III consists of 25 cases that had been on liver treatment and complained of a return of symptoms.

Two cases have been omitted from this series owing to other complications: both had relapsed on full doses of raw liver. In one an epithelioma had been removed from the tongue; later, a block dissection of the cervical glands was performed. The patient died from pneumonia and cardiac muscle failure after readmission to the Manchester Royal Infirmary. Necropsy confirmed the diagnosis of coexisting pernicious anaemia. The other died, while an in-patient, from broncho-pneumonia and acute colitis, having received treatment for only five days.

TREATMENT

The treatment given in this series of cases may be considered under two headings, according as the patients received fresh or desiccated preparations of hog's stomach.

Raw Tissue of Hog's Stomach

In the preliminary report already referred to[1] several cases were described that had been given uncooked fresh hog's stomach preparations. In all, about ten cases have been so treated, but the difficulty of continuing this treatment after the patient's discharge from hospital led to the replacement of the fresh by the desiccated preparations on transference to the out-patient department. These cases are marked with an asterisk in Table I.

One patient, however, was conveniently situated, so that it has been possible to continue the raw tissue therapy. This case was described in the earlier paper as Case III.

Case 1 (Table I)

It was a typical case of pernicious anaemia. The initial blood count showed: red blood cells 1,910,000 per c.mm., white blood cells 7,600; haemoglobin 50 per cent.; colour index 1.3. The patient was treated with 250 grams of uncooked fresh mucous membrane of hog's stomach daily, and very rapidly improved, so that by the seventy-eighth day the blood count was: red blood cells 5,072,000, white blood cells 8,300; haemoglobin 84 per cent. He returned to full-time work; since then he has been in normal health.

The dose has been gradually adjusted; at the present time he takes 1,000 grams of uncooked fresh tissue per month. For convenience this is divided into daily doses of approximately 350 grams, so that the whole of the month's supply is consumed in three days. He takes no more until the next month's supply is due. The tissue is carefully washed in cold water, examined macroscopically for parasites, and then minced. It keeps well in a refrigerator for long periods; the patient has not had any difficulty in keeping it the maximum of two and a half days before taking the last portion. By the administration of rather larger doses than this maintenance dose the blood picture can be kept at a somewhat higher level, but there has not been any noticeable difference clinically. He is perfectly well after sixty-four weeks on this diet; he is doing his full-time work, and has put on weight. The treatment is being continued.

During the treatment there was a marked eosinophilia, reaching its maximum (19 per cent.) at the twenty-seventh week, but was less than 5 per cent. after the forty-fifth week. The leucocytes have varied between 6,000 and 14,000, being high when he had a cold, and again when he had a septic finger.

Desiccated Preparations

In the earlier experiments, as reported previously, the desiccated hog's stomach was mixed with chocolate and lactose. This made a very palatable drink, but many patients have a distaste for milk—the medium chiefly used. I have therefore been using the preparation without these added constituents. This has certain advantages, in that the bulk of powder is less per dose, while it can be taken in milk or water as desired, or may be mixed with other foodstuffs *provided that heat is avoided.*

The preparation used for routine treatment is a desiccated whole hog's stomach ("extomak"), kindly prepared for me by Messrs. Benger's Food, Ltd., of Manchester. It is a very light, biscuit-coloured powder, insoluble in water and organic solvents; 25 grams are

* From the Laboratory for Clinical Investigations and Research, Manchester Royal Infirmary.

equivalent to 100 grams of the fresh whole hog's stomach. It mixes well with milk and such media. Owing to its very powerful peptic activity (see below) it is advisable to mix the required dose just prior to its administration, otherwise it arrives before the patient as a junket-like mass—a much less palatable form to most patients.

The dose employed initially is 25 to 30 grams daily, divided into three portions. This is reduced to 10 to 20 grams daily as the blood picture becomes more normal, the average maintenance dose being about 10 to 12 grams daily. In some cases the maintenance dose is larger or smaller than this amount; the needs in each individual case have to be estimated by careful observation and regular blood counts. The dose may have to be increased or diminished according to the season of the year or the health of the patient, common colds and influenza having very profound effects on the blood counts in many of these cases.

An important practical point arises here. The dosage employed must be measured *by weight*. Owing to the very light, relatively bulky nature of the powder, the usual method of measuring by spoonfuls frequently leads to the ingestion of a dose which is much less than that prescribed, with obvious consequences.

Adjuvant Medicines

The use of hydrochloric acid in association with this form of treatment does not appear to be necessary or to have any marked effect. This is in contrast to its use in conjunction with liver, where it is often necessary for the complete relief of gastro-intestinal symptoms.[13] During their period as in-patients a few of the cases were given certain iron preparations and occasionally arsenic, according to the prescription of the honorary physician in whose ward they happened to be. There was no noticeable difference in the speed of remission in any of these patients, compared with those who were not receiving such additional treatment. In this connexion it is interesting to compare the result obtained in Case 71 (see p. 87). It should be mentioned that in most cases after discharge from hospital these adjuvant medicines have been discontinued, only the hog's stomach preparations being taken regularly.

RESULTS OF TREATMENT

The results of treatment in 83 of the 108 cases contained in this paper are conveniently summarized in Tables I and II.

In Columns A the initial blood condition (red blood cells and haemoglobin) of each patient is shown before the commencement of hog's stomach therapy. The corresponding values obtained at the *last* blood count taken are recorded in Columns B, and do not represent the maxima obtained. In the last column are given the total periods of observation (in weeks) of each patient from the beginning of treatment until the last blood count was taken (Columns B). These periods do not represent the time taken to reach normal values in these cases. The leucocyte and differential counts have been omitted for economy of space, and are irrelevant to the present discussion.

The results may be classified in the three groups previously mentioned.

Group I.—No Previous Treatment

Table I, 52 cases. None of these had had any treatment before coming under my observation—apart from the usual tonics containing iron, arsenic, "phosphates," etc. They were treated with preparations of hog's stomach as above, but in Case 1 (see above) the uncooked fresh tissue has always been taken. The nine other patients, indicated by an asterisk, were similarly treated while in-patients, but continued on desiccated

A = Blood count before treatment with hog's stomach.
B = Present blood count.
* = Received uncooked fresh hog's stomach while in-patients.

preparations after discharge from hospital. They are thus considered together with the remainder of the cases. Several patients were treated as out-patients, attending the laboratory daily for observation and treatment.

It will be observed that the periods of observation varied from seven to sixty-four weeks, giving an average of 32.4 weeks; seven cases have been under this form of treatment for more than fifty-two weeks, and fifteen for more than forty weeks.

The majority of the cases showed initial red cell counts less than 3 million, and thirty-one of them less than 2 million. The most recent counts are interesting, since they indicate a very marked tendency towards high red cell counts, but haemoglobin values of relatively less increment. This is not marked until the red cells become more numerous than approximately 5.5 million, after which the colour index shows a steady fall. Six cases have given higher counts, but at the present time only four are over 6 million, one of these being 7.25 million.

The haemoglobin tends to lie between 90 and 110 per cent., but where the dose is rather too small, or the patient discontinues the treatment for a time, it frequently falls to about 80 to 90 per cent. This rapidly improves with slightly increased doses.

The leucocytes showed an average initial count of 4,530, and an average final count of 6,500.

The following case illustrates this group very well, and is typical of the result obtained.

Case 18 (Table I)

A labourer, aged 49, was admitted to hospital complaining of anaemia, weakness, and paraesthesiae in the fingers for ten weeks before coming under observation. In the last few weeks the pallor had increased and numbness in the feet had developed. His appetite was good and the bowels were regular; there was no complaint of diarrhoea, sore tongue, indigestion, or loss of weight. Family and previous medical histories revealed nothing of note.

Examination.—Lower teeth were very septic; tongue was smooth but clean. He weighed 8 st. 8 lb. Spleen and liver were not enlarged, and there were no alterations in the reflexes. Wassermann reaction was negative. Fractional gastric analysis showed achylia gastrica. Blood count: red blood cells 1,400,000, white blood cells 6,500; haemoglobin 46 per cent.; colour index 1.6; platelets scanty; anisocytosis and poikilocytosis marked; polychromasia present; megaloblasts and nucleated red cells also seen.

The patient was given a desiccated preparation of hog's stomach equivalent to 280 grams of fresh tissue daily, reduced later to 15 grams of desiccated preparation, together with a hydrochloric acid[13] mixture. There was a very prompt response to this treatment, the blood picture rapidly improving, so that one week after discharge from hospital—the sixty-fifth day of treatment—it showed: red blood cells 5,060,000, white blood cells 9,200; haemoglobin 104 per cent.; colour index 1.04; platelets abundant; and slight anisocytosis. The present condition, after forty-nine weeks of treatment, is indicated in Table I.

Results.—All the patients in this group are well after an average period of thirty-two weeks, and none have shown any indication of relapse at the time of writing.

Of these 52 cases, 46 (88.5 per cent.) are now in normal health, free from symptoms, and doing their original full-time work. (Included in this figure are a few male patients now perfectly fit but unable to get employment.)

Three patients are quite well, but still have symptoms of early postero-lateral sclerosis; one suffers from paralysis agitans, but is otherwise well (Case 15); the remaining two patients (Cases 8 and 19) are progressing very well, but have only recently been discharged from hospital, so that their blood counts are not yet normal. The latter patient took no treatment for two weeks, but is also rapidly improving; both will be fit for work in a very short time, as there are no signs of nervous involvement.

Twenty-seven of these patients complained of various paraesthesiae affecting their hands and feet; after treatment with hog's stomach only one has definite numbness in the fingers, the remainder being cured or suffering only from occasional attacks.

Six patients had definite postero-lateral involvement of the spinal cord; three are so much improved that they have returned to full-time heavy manual work; two are much improved but are not working; one is unchanged as regards the nervous condition.

Group II.—Relapsed Cases after Liver Treatment

Table II summarizes the 31 cases in this group. All the patients had taken liver at some period before coming under my observation and had had definite relapses, as shown by the clinical conditions and the blood counts (Columns A). In most cases the relapse was caused

* Discontinued treatment for 8 weeks.
† Discontinued treatment for 4 weeks.
‡ See text.
§ Discontinued treatment for 8 weeks.

either by discontinuance of the treatment or by the ingestion of inadequate active doses, due partly to excessive cooking of the raw liver. These cases were reinvestigated in this laboratory, and treated according to the routine followed in Group I.

Results.—In this group the results are not so striking as the previous ones, since the patients usually came under observation earlier, and hence the initial blood counts were on an average higher than in those cases

diagnosed for the first time. The average initial blood picture showed: red blood cells, 2,500,000; haemoglobin, 63 per cent. These patients have been under observation for a period of eight to seventy weeks, with an average of 23.5 weeks. During this time none has shown any signs of relapse, or developed postero-lateral involvement of the spinal cord.

Twenty-one patients (67.7 per cent.) are very well and doing full-time work; eight (25.8 per cent.), although not working, are also well and have no symptoms, making a total of twenty-nine patients (93.5 per cent.) in normal health again; two (6.4 per cent.) are well except for slight postero-lateral involvement, which is very much better than before treatment; none has failed to respond satisfactorily to the treatment.

Case 77 (Table II)

This case is of considerable interest, since, after discharge from hospital, the patient became pregnant. She was seen regularly at intervals of one month, later fortnightly, and was kept on a daily dose of 20 to 30 grams of desiccated hog's stomach. At no time during the period of gestation did the count fall below 4,200,000 red blood cells and a haemoglobin percentage of 78. Two weeks before parturition the count was: red blood cells 4,256,000, white blood cells 5,900; haemoglobin 90 per cent.; colour index 1.05. Three weeks after parturition the red blood cells were 4,440,000, white blood cells 4,800; haemoglobin 78 per cent.; colour index 0.9. The count fourteen days later is given in the table.

The following two cases have been chosen to illustrate this group; the first was treated as an out-patient from this laboratory, the second as an in-patient.

Case 54 (Table II)

A marine engineer, aged 61, attended the out-patient department of the Manchester Royal Infirmary complaining of considerable weakness, dyspnoea on exertion, indigestion, and paraesthesiae in the hands and feet. He had been unable to work for two years. There was no sore tongue or diarrhoea, but he was very constipated. For about four months he had noticed the progressive development of a yellowish pallor over the body. He had not lost much weight, and his appetite was fairly good.

Previous Medical History.—He had been treated for pernicious anaemia six months previously, but had not continued the liver diet. Family history disclosed nothing of note.

Examination.—Pale lemon-yellow colour; conjunctivae deep yellow; considerable pyorrhoea present and teeth very septic; liver and spleen were not enlarged, and no other abnormality was found. Wassermann reaction was negative. Blood count was as follows: red blood cells 976,000, white blood cells 6,200; haemoglobin 24 per cent.; colour index 1.3; platelets very scanty; anisocytosis and poikilocytosis very marked. Fractional gastric analysis showed achylia gastrica.

Day of Treatment	Erythrocytes	Leucocytes	Percentage Haemoglobin
1	976,000	6,200	24
5	1,576,000	2,700	35
13	1,816,000	3,500	50
27	3,216,000	4,500	80
39	3,958,000	5,400	88
55	5,168,000	5,100	97
69	5,072,000	5,800	95
175	5,720,000	7,400	98

He was given a daily dose of 25 grams of an active desiccated hog's stomach preparation and attended this laboratory as an out-patient throughout the treatment. No blood transfusion was given. The very rapid and progressive response obtained with this treatment is indicated by the figures in the preceding table. He is now in perfect health and free from symptoms.

Case 62 (Table II)

A shopkeeper, aged 54, first came under observation at the Manchester Royal Infirmary on October 9th, 1928, complaining of lassitude, weakness, and an increasing pallor since March of that year. It became more noticeable in June, when shooting pains in the back and legs incapacitated him from walking. His appetite was poor, and he had had attacks of vomiting for two to three weeks. There was no history of sore tongue or diarrhoea, but the bowels were constipated. The feet swelled occasionally and the left foot felt numb. There was no marked loss of weight.

Previous Medical History.—Appendicitis at 16 years of age had been treated medically. For some years he had worked in a rubber factory and had been troubled with gastric disturbances. He stated that he had had lead poisoning several times; and neuritis during the last twelve years. He had been a shopkeeper for the last ten years. His family history disclosed that his mother died of diabetes mellitus, and that his father died, aged 78, from gangrene.

Examination.—Marked yellow pallor; teeth artificial; tongue furred and flabby; weight 9 st. 7 lb.; knee-jerks present; spleen slightly enlarged. Blood count: red blood cells 1,150,000, white blood cells 4,800; haemoglobin 25 per cent.; colour index 1.17.

The patient was treated with liver (four ounces), iron, arsenic, and salol, and improved very much, so that on his discharge from hospital on November 28th his weight was 10 st. 10 lb., and the blood count: red blood cells 4,200,000, white blood cells 6,200; haemoglobin 86 per cent.; colour index 1.02; differential count normal.

He was not seen again until July 25th, 1930, when he was readmitted to the Manchester Royal Infirmary with a recurrence of the original symptoms of lassitude, pallor, loss of appetite, and shortness of breath on exertion. This time also he complained of a constant pain in the epigastrium, loss of weight, and had had paraesthesiae in both legs for the last eighteen months. He stated that he had been taking lightly cooked liver (2 lb. per week), with iron and arsenic mixtures, but no hydrochloric acid.

Examination.—Pale lemon-yellow colour; teeth artificial; tongue clean; weight 9 st. 5 lb. Left leg was wasted to a greater extent than the right; left knee-jerks absent, and there was difficulty in walking. Wassermann reaction was negative. The blood count on July 31st showed: red blood cells 1,440,000, white blood cells 5,800; haemoglobin 50 per cent.; colour index 1.8. Fractional gastric analysis showed achylia gastrica.

He was given a daily dose of 30 grams of desiccated hog's stomach in cold milk, and hydrochloric acid (*B.P.*, dil. mxxx) with each meal. The improvement was extremely satisfactory, and he was discharged on August 30th with a blood count as follows: red blood cells 3,600,000, white blood cells 3,300; haemoglobin 98 per cent.; colour index 1.3. After sixteen weeks of treatment the count showed: red blood cells 6,100,000, white blood cells 7,400; haemoglobin 102 per cent.; colour index 0.8. He is in perfect health, doing his full-time work, has put on weight, and is free from all symptoms.

Group III.—Return of Symptoms after Liver Treatment

The patients in this group had been taking liver diet in some form or other. Many of them had discontinued the treatment, but others had relaxed the dose or went cooking the liver too much. Two had been taking a type of "liver extract" that I have found to be unsatisfactory.

The initial erythrocyte counts in these cases were relatively high, but the colour indices were greater than unity in all of them. Although these patients had relatively good blood counts, they complained of a very marked return of the original symptoms—for example weakness and shortness of breath, sore tongue, gastro-intestinal disturbance, paraesthesiae in fingers and toes, etc. In nearly all these cases the pepsin and hydrochloric acid mixture had been discontinued for many months.

They were given desiccated hog's stomach, 15 to 2 grams daily as above, in place of the liver diet.

Results.—The twenty-five cases in this group have been under observation on hog's stomach treatment for a

average of twenty-two weeks. All the patients are very well and obviously in much better health than before receiving this treatment, while the symptoms have entirely disappeared. A few of them were also given the hydrochloric acid mixture.

The average blood count for the whole group before treatment showed: red blood cells, 4,370,000; haemoglobin 89 per cent.; after treatment during an average of twenty-two weeks there were 5,160,000 red blood cells and a haemoglobin percentage of 95.6.

Summary of Results

The results in 52 cases of untreated pernicious anaemia and in 31 definitely relapsed cases (Groups I and II) indicate that 92.7 per cent. (77 patients) are perfectly well and free from symptoms of any kind, while 6 per cent. (five patients) are well, but are still suffering from some degree of nervous impairment, although this has much improved. Not one failed to respond to treatment satisfactorily. These figures should be compared with the corresponding figures of 50 per cent. and 15 per cent. obtained in patients treated by liver.[14]

From these results, obtained by the use of active preparations of hog's stomach, both fresh and desiccated, in 108 cases of pernicious anaemia, it is abundantly clear that this is the best treatment so far known for the disease. While liver diet is also an excellent method of treatment, there are many cases that do not respond to this form of therapy. On the other hand, when *adequate* treatment has been given with an *active* preparation of hog's stomach no case of true pernicious anaemia, from my own experience, has failed to respond.

The use of a mixture of hydrochloric acid and pepsin, in addition to liver diet, for the relief of certain gastro-intestinal symptoms in pernicious anaemia has been discussed in an earlier paper.[13] In the newer treatment with hog's stomach this mixture is rarely necessary, and none of the symptoms have, so far, been found to recur.

CHANGES IN THE BLOOD PICTURE

In all the cases recorded in this paper the improvement and good health have been maintained. Many patients, however, who have continued on full doses of hog's stomach after reaching normal blood counts have shown tendencies towards excessive erythrocytic reaction until the doses have been reduced. An increase to over 6 million red cells has been observed in seven cases (six in Group I, one in Group II), but three have returned to normal levels after suitable reductions in dosage. The others have only recently reached these higher values, and have not been examined since the reductions. All these cases showed a marked "lag" in haemoglobin increment over 110 per cent., so that the colour indices have fallen steadily with increasing red cell counts over 6 million. This has automatically corrected itself with the return of the erythrocyte counts to normal value.

The question then arises of the possibility of producing a polycythaemia as a result of continued large doses of hog's stomach. So far as I am aware no such cases have been recorded in which liver or liver extracts have been used, and the subsequent progress of these cases is being closely observed. The point is illustrated by the following case.

Case 26 (Table I)

A foreman lockgate-keeper, aged 49, complained of weakness and dizziness, associated with frequent nausea and headaches, for eighteen months prior to coming under my observation. He had indigestion and flatulence, and paraesthesiae in the hands and feet, but had only had a sore tongue for about two weeks. There was no history of diarrhoea, constipation, or loss of weight, but his appetite was poor. He had noticed the development of a gradually increasing yellow colour over the whole body. Apart from a slight attack of malaria twenty-five years previously, there was nothing of note in his previous medical history. His son suffers from purpura haemorrhagica.

Examination.—A slightly built man, with very marked yellow pigmentation of the conjunctivae and sclerotics, slightly less marked over the whole body. Tongue clean, teeth artificial. Nothing else found abnormal. Wassermann reaction was negative. Fractional gastric analysis showed achylia gastrica. On March 31st, 1930, his blood count showed: red blood cells 1,700,000, white blood cells 3,600; haemoglobin 39 per cent.; colour index 1.1; very marked anisocytosis and poikilocytosis; platelets scanty; nucleated red cells, polychromasia, and megaloblasts present.

The patient was given 28 grams of desiccated hog's stomach daily, and rapidly responded to this treatment (see below), the reticulocytes rising to 37 per cent. on the nineteenth day. On May 12th his blood count showed: erythrocytes 5,912,000, white blood cells 5,100; haemoglobin 98 per cent., colour index 0.83.

The dosage was reduced to 10 grams daily of the desiccated preparation, and the patient was seen at monthly intervals. The erythrocytes steadily increased in number, but the haemoglobin did not show a correspondingly rapid rise, so that the colour index fell below unity. On October 21st the blood count was as follows: red blood cells 7,260,000, white blood cells 5,500; haemoglobin 100 per cent., colour index 0.68. There was no eosinophilia at any time. A similar observation was made in Case 3 (Table I), but on reducing the dose for this patient the erythrocytes fell, while the colour index again increased.

The patient was perfectly well, and did not complain of any ill-effects from this excessive blood reaction. All treatment, however, was discontinued, and three weeks after these notes were written the count showed: red blood cells 5,360,000, white blood cells 5,000; haemoglobin 90 per cent.; colour index 0.9.

Date	Erythrocytes	Percentage Haemoglobin	Colour Index
1930 March 18	1,700,000	38	1.1
April 11	2,160,000	52	1.2
April 17	2,740,000	58	1.06
April 26	4,030,000	83	1.03
May 12	5,910,000	98	0.8
June 16	5,780,000	92	0.8
July 14	6,560,000	108	0 8
August 12	6,750,000	109	0.8
Sept. 9	6,590,000	96	0.69
Oct. 21	7,260,000	100	0 68
Nov. 11	5,360,000	90	0.9

Progress of Improvement in Blood Picture.

From a general survey of the results obtained in this series of cases the progress of improvement in the blood picture appears to be somewhat as follows. The erythrocyte count and the haemoglobin value increase simultaneously at the beginning until the haemoglobin is approximately 40 to 60 per cent. (or perhaps a little higher, according to the individual), when it remains roughly constant for a short time until the red cells have reached 3.5 to 4 million. The haemoglobin then continues to improve until it reaches 95 to 100 per cent., by which time the erythrocytes, if the dosage is not reduced, are approaching 5 million or a little more. Occasionally the position may be reversed, the haemoglobin improving progressively while the erythrocytes show the first "lag." In some cases this step-like progress is not shown.

From this stage only the erythrocytes increase, the haemoglobin very rarely rising above 110 per cent. Thus the colour index throughout the course of the treatment shows a general tendency to fall from above to below unity as the red cells increase—that is to say, the colour index varies inversely with the height of the erythrocyte counts. An erythrocyte count approximating to a

polycythaemia thus produces a colour index of a marked secondary type of anaemia.

This is so characteristic when it does occur that it suggests very strongly (*a*) the possible value of iron at this stage in conjunction with the treatment; (*b*) that the erythrocytes and haemoglobin may be produced by entirely different mechanisms, although to some degree interdependent, and possibly even at different sites. The importance of this consideration upon the general question of anaemia is being investigated.

The Reticulocyte Response

It is well known as a result of the work of Minot and others[15] that the reticulocyte response varies inversely with the initial erythrocyte level. Confirmation has been obtained in this laboratory. With this as a basis of comparison the observations on the reticulocyte responses following this form of therapy which have been published by others fall considerably short of those obtained in my series of patients described above. Thus, where they have reported "peaks" of 15 to 20 per cent. of reticulocytes, in cases with similar initial blood pictures I have obtained 25 to 40 per cent.—more usually the latter—and in some cases even higher. I have found by experiment that the use of an inadequate dose or a less active preparation usually results in such lower reticulocyte responses, which may also be delayed in reaching their maxima for perhaps fourteen days or more.

COMPARISON OF METHODS OF TREATMENT

In a previous paper[14] the results of treating pernicious anaemia with iron and arsenic in 47 cases were compared with those obtained by the liver treatment (33 cases). These figures represented the average percentage increases of erythrocytes, haemoglobin, and leucocytes respectively after a period of forty-five days' treatment in hospital in each case. For comparison, I have now added the corresponding results obtained by this newer treatment with hog's stomach, and Table III indicates the relative values of the three forms of treatment in exactly comparable cases. In order to avoid complications, the figures are compiled from the 52 cases that have had only hog's stomach treatment.

TABLE III

Treatment	No. of Cases	Average Percentage Increase in 45 Days		
		Erythrocytes	Haemoglobin	Leucocytes
Iron, arsenic, blood transfusion	47	+ 46	+49	− 8
Liver diet	33	+ 94	+77	+41
Hog's stomach ..	52	+157	+91	+41.5

It will be observed that the rates of improvement in the erythrocyte counts and haemoglobin values are, respectively, 1.7 and 1.2 times quicker than those obtained with the liver treatment, but 3.4 and 1.8 times respectively than the older iron-arsenic-blood-transfusion treatment.

The relative merits of these methods of treatment are extremely well illustrated by the following case.

Case 71 (Table II)

A clerk, aged 41, was admitted to the Manchester Royal Infirmary for the first time on November 4th, 1924, complaining of increasing anaemia (six weeks' duration), weakness, vomiting (several months' duration, but worse during the five weeks prior to admission), vertigo, and shortness of breath on exertion. There had been some diarrhoea, indigestion, and flatulence, but no loss of weight or sore tongue.

Previous Medical History.—Psoriasis vulgaris, eczema, erythema multiforme at various periods; "gastritis" in 1915; was "gassed," and had septicaemia during the war period. Family history disclosed that his father died of Bright's disease, and one sister died of dropsy.

Examination.—Teeth septic; no enlargement of spleen or liver; knee-jerks present; weight 10 st. 13 lb., nothing else of note. Wassermann reaction was negative. Blood count: red blood cells 1,336,000, white blood cells 6,800; haemoglobin 26 per cent.; colour index 1.05; platelets scanty; very marked anisocytosis and poikilocytosis; megaloblasts present.

Treatment mainly consisted of iron and arsenic preparations. He was discharged slightly improved on December 15th, and remained in a moderate state of health for twelve months, when the symptoms returned as before.

On September 15th, 1926, he was readmitted to hospital, but this time soreness of the tongue was also present, together with epistaxis and intermittent pain in the legs.

Examination.—Skin, mucous membranes, and conjunctivae a markedly yellow colour; teeth very septic, with marked pyorrhoea; liver slightly enlarged to two inches below the costal margin; knee-jerks present. Blood count: red blood cells 948,000, white blood cells 6,000; haemoglobin 20 per cent.; colour index 1.05.

He was treated with large doses of arsenic (oral and intramuscular), iron, streptococcal vaccines, salol, and artificial sunlight, and again showed some slight improvement. When discharged on January 18th, 1927, the blood picture was: red blood cells 1,440,000, white blood cells 4,800; haemoglobin 36 per cent.; colour index 1.3; platelets scanty; marked anisocytosis and poikilocytosis.

After a second relapse, he was again an in-patient from July 6th to August 24th, 1927. He complained of similar symptoms as previously, but not diarrhoea. The blood count showed: red blood cells 1,160,000, white blood cells 10,200; haemoglobin 30 per cent.; colour index 1.3; platelets scanty; anisocytosis and poikilocytosis very marked; polychromasia and punctate basophilia also present.

The previous treatment was renewed vigorously, with the addition, for the first time, of four ounces of lightly cooked "potted" liver per diem. This time he showed a much better response to treatment, probably due to the liver, and the blood count on discharge from hospital was: red blood cells 3,340,000, white blood cells 4,400; haemoglobin 70 per cent.; colour index 1.0.

He was sent home to continue this liver diet (four ounces daily), but relapsed a third time, being readmitted from January 8th, 1929, to February 16th. The symptoms were similar to those previously recorded, and he had a marked lemon-yellow colour; the tongue was pale and flabby, and the lower teeth were still very septic. Examination did not reveal any other abnormal features. Blood count: red blood cells 1,064,000, white blood cells 4,600; haemoglobin 26 per cent.; colour index 1.3.

He was again given vaccines, large doses of iron and arsenic, and four ounces of lightly cooked liver per diem until his discharge, when the blood count was: red blood cells 2,780,000; haemoglobin 58 per cent.; colour index 1.03. Four months later, on this treatment, the count was: red blood cells 3,016,000; haemoglobin 82 per cent.; colour index 1.3.

He was not seen again until December 11th, when he was admitted as an urgent case to the Manchester Royal Infirmary with the following count: red blood cells 696,000; haemoglobin 14 per cent.; colour index 1.6. He was in a very bad, semi-comatose condition, with a marked lemon-yellow colour all over the body.

A blood transfusion (one pint) of citrated blood (Group IV) was given, and the earlier treatment continued. To the daily four ounces of fresh liver was added liver extract (half an ounce of a fluid preparation); hydrochloric acid and pepsin were also given with each meal (gastric analysis showed achylia gastrica). On February 15th, 1930, he was discharged from hospital on a diet consisting of four ounces of liver, together with liver extract and hydrochloric acid. The blood count at that date was: red blood cells 3,740,000, haemoglobin 80 per cent.; colour index 1.06—the best count recorded since he came under observation.

(I am indebted to Dr. C. H. Melland for the above notes on this patient, who was under his care in the Manchester Royal Infirmary.)

The patient attended this laboratory, as an out-patient, from this time onwards, at frequent and regular intervals, but there was no improvement on the last count, even when the dose was increased to eight ounces of raw liver daily.

On July 8th the blood count was: red blood cells 3,240,000; haemoglobin 92 per cent.; colour index 1.4. In view of this

the whole of the previous treatment was discontinued, and replaced by 28 grams daily of desiccated whole hog's stomach. *The blood picture* showed an immediate and progressive improvement such as had never been observed before in this patient. The most recent blood count shows: red blood cells 5,430,000; haemoglobin 92 per cent. The patient himself is perfectly well, and states that he has never been so fit for over seven years. He is now working, and starting to play football.

GENERAL OBSERVATIONS

Active desiccated preparations of hog's stomach should have extremely good peptic activities. An examination of the commercial desiccated products offered by several wholesale houses in Europe and America has disclosed very widely varying peptic activities in different samples. If this pepsin content is also an approximate index, as I think it may be, of the coexisting "anti-anaemic" value of the product, then the lower and slower responses to treatment with such preparations obtained by certain other workers is explained.[16]

Many of the patients have been re-examined at intervals by fractional gastric analyses, but so far no alteration has been noted in the achylia gastrica.

It is important that the patient should understand that, as with liver, hog's stomach does not constitute an absolute cure for the condition. One patient, however, under observation at present is perfectly well after nearly twelve months of abstinence from all forms of treatment. As a rule, a greater or less maintenance dose must be taken at fairly regular intervals, so far as is known, for an indefinite period, and possibly for life. This involves regular blood counts for the control of the patient's condition, and it should be borne in mind that the blood picture is profoundly affected by colds and other infections: it is advisable at these times to increase the dose temporarily.

This maintenance dose may be taken in small regular daily amounts (this is usually the most satisfactory method), or, as has been well illustrated in Case 1 above, it may be administered in relatively large doses for a day or two every few weeks. A somewhat similar observation has been made by Riddle and Sturgis,[17] who gave massive doses of liver extract (equivalent to 3 kg. fresh liver) to three patients. It appears, therefore, that the maintenance of good health and a normal blood condition in these cases requires the supply of a definite minimal quantity of the active principle within certain time limits, probably fourteen to twenty-eight days, the body being unable to store this necessary, as yet unknown, substance, at any rate in an available form, for more than this short period.

At the present time fresh hog's stomach is the cheapest and the most active form of treatment, while a certain desiccated preparation available is as cheap as fresh liver when taken in the average maintenance dose.

SUMMARY

1. The earlier observations upon the value of hog's stomach have been extended to 108 cases of pernicious anaemia, and the results are here discussed.

2. Treatment has been described using fresh and desiccated preparations of hog's stomach tissues. The dose and administration have been indicated.

3. After periods of observation up to eighteen months no relapses have occurred, and all the cases have done well.

4. This new form of treatment for pernicious anaemia with active preparations of hog's stomach has given highly satisfactory results—undoubtedly better than with liver, while the relative effective dose is less than the liver dose.

5. More than 92 per cent. of the patients treated with hog's stomach are perfectly well, and the majority are doing their full time work. A further 6 per cent. are much improved, but still suffer from varying degrees of nervous impairment.

6. *Hog's stomach therapy is superior to liver diet in* the speed of remission of the condition, the erythrocytes and haemoglobin increasing 157 per cent. and 94 per cent. respectively, compared with 90 per cent. and 77 per cent. respectively with liver under comparable conditions.

7. Hog's stomach therapy has qualitative effects on the blood picture similar to those of liver, but the erythrocytes and haemoglobin increase in a characteristic step-like manner in many cases. The colour index varies inversely with the red cell count.

8. Eosinophilia is frequently seen, but not in every case.

9. Clinically, the immediate results are similar to those obtained with liver. They are more prompt and, ultimately, the normal health is reached more quickly; work is resumed sooner; and all the gastro-intestinal symptoms appear to be relieved. This is not always the case with liver treatment, hydrochloric acid and pepsin being frequently required in addition to relieve the indigestion, flatulence, and occasional sore tongue.

10. Achylia gastrica persists despite the treatment.

11. Hydrochloric acid and pepsin do not appear to be necessary for the relief of symptoms with this form of treatment.

12. There is a minimum dose of hog's stomach to maintain the normal health of each patient. Regular blood counts are essential for the control of this dose, owing to seasonal variations and the profound effects of even minor infections.

13. Hog's stomach in normal doses readily produces an excessive erythrocytic response, approaching polycythaemia, and several cases with counts over 6 million are now under observation.

14. Fresh hog's stomach can be taken in adequate doses for a few days every three to four weeks with a maintenance of normal health.

15. Several cases with early postero-lateral involvement of the spinal cord have shown remarkable improvement, and paraesthesiae of hands and feet (without alteration of reflexes) have been almost completely cured in nearly every case. These have always been the symptoms most resistant to treatment.

I have to thank the honorary physicians of the Manchester Royal Infirmary for kindly supplying me with the clinical material essential for this work, and also Professor H. S. Raper, F.R.S., for his continued interest. The majority of the blood counts have been done by the clinical pathologists of the Manchester Royal Infirmary, and by Dr. Agnes Bodoano in this laboratory, to all of whom I express my deep appreciation of their invaluable assistance.

Addendum.—Since this paper was written this series has been extended to 133 cases, and the periods of observation in Tables I and II can be increased by eight weeks in each case. Those cases with relatively low final blood counts have all reached normal values. There is no material alteration in the other figures requiring comment.

REMOVAL OF ADENOIDS—A SIMPLIFIED TECHNIQUE

BY

O. POPPER, M.B., F.R.C.S.ED.

SURGEON IN CHARGE OF THE EAR, NOSE, AND THROAT DEPARTMENTS, QUEEN'S HOSPITAL FOR CHILDREN

Of the so-called " minor surgical procedures " in children, the complete removal of adenoid hypertrophies must rank as the most important, and, being a blind manœuvre, also the most difficult. Those who perform this operation frequently will agree that a certain knack must be acquired in order to sweep the entire adenoid mass out of the rhinopharynx in one clean stroke. The adenoid operation is one of those rare survivals in surgery where a difficult technique has been developed to perfection in order to overcome an inherent structural fault of a stereotyped instrument. Even those who have regular opportunities of performing the operation exhibit a lack of certainty. It is essentially a planing operation, the adenoid mass being shaved off from its broad attachment in one clean sweep. Its ancient label of " curettage," the method used very long ago, describes the modern operation as fittingly as it would the removal of a layer of skin for a Thiersch graft. The instrument used should be called a plane. If an instrument is used as a rake or scraper, it must have a certain shape best suited for this purpose; when this instrument is to function as a plane, however, a totally different set of mechanical factors is brought into play, and the old shape must be modified to suit new conditions.

The " Knack " of the Operation

With the ordinary instrument the cutting blade is 1/2 to 3/4 inch above the line of force as transmitted through the handle (Fig. 1). In order to " hug the post-

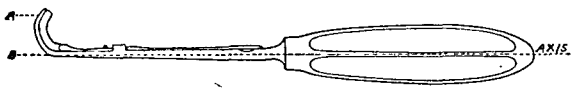

FIG. 1.—Outline of Sir StClair Thomson's modification of the Gottstein curette. A, Cutting edge; B, Axis.

nasal wall," an essential in effecting the complete removal, the cutting edge describes a curved path corresponding to the curvature of the particular post-nasal space which is being operated upon (Fig. 2, (*a*), (*b*), (*c*)). The knack of the expert operator is that he is able to transmit adequate pressure in such a manner that the resultant, speaking mechanically, of the force he applies and of the opposing force of the blade, which is at a higher level in the post-nasal space, will give the cutting edge the desired curved direction; it also signifies that the blade is always presented at an efficient cutting angle. During the operation the handle rotates upwards, *the centre of rotation being the edge of the blade.* The latter must be made to describe a path corresponding to the curvature of the rhinopharynx if complete removal of adenoids is to be achieved. That is the crux of the matter. In Figure 1, A represents the edge of the blade and is the pivot around which the instrument must rotate. There is very little latitude here for an allowable margin of error. The completeness of removal will depend upon how near to point A the centre of rotation has been kept. At A the removal will be complete, whereas the further it gets towards B the more incomplete will be the removal. As B is in line with the axis of the handle there is a constant tendency on the part of the instrument to pivot on this latter point. Furthermore, the curvatures of the different post-nasal spaces (Fig. 2) vary ; some are flat, others more recessed, all calling for some slight modification of pressure and rotation. Only one who constantly does this work can be expected to be able to compensate for all these factors.

My attempts at teaching this technique convinced me that the difficulty or inability on the operator's part to guide the blade accurately down the curvature was primarily due to the fact that the blade and handle were in two different planes. It seemed to me that there was no reason whatever why the blade and the handle should not be placed in the same plane. I therefore instructed Messrs. Mayer and Phelps to make the instrument illustrated (Fig. 3) for me. The cutting edge of this adenoid

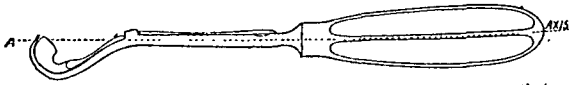

FIG. 3.—Outline of the author's adenoid plane. Note that the cutting edge (A) is in the axis of the instrument.

plane is in direct continuity with the axis of the handle. In order to clear the soft palate, that part of the instrument between the head and the handle is curved downwards. The major technical difficulties of the operation vanish with this construction. This plane cannot rotate about any point other than the edge of the blade, corresponding to A in Figure 1. There is no need to acquire any knack, because *the operation has been converted from an indirect into a direct cutting manœuvre.* The surgeon need not direct the blade. *The instrument will guide itself down the post-nasal wall, as it must do, and will adapt itself automatically to the varying curvatures of the different post-nasal spaces.* All that is necessary is to apply moderate pressure throughout the sweeping-down movement. This also means that whatever the position of the instrument the blade is always at the cutting angle. The blade is set at an angle of 45 degrees to the handle, which I have found to be most suitable. In the older types of instrument this angle seems, in some cases, to have been determined by the whim of the

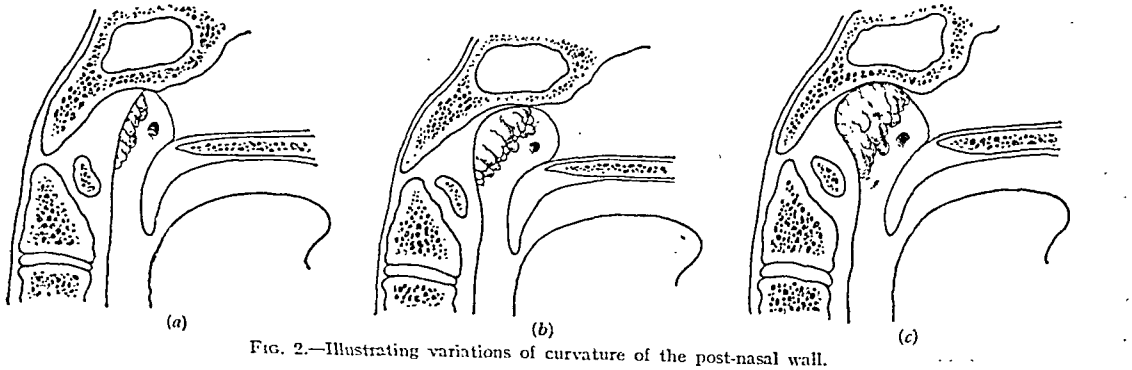

FIG. 2.—Illustrating variations of curvature of the post-nasal wall.

particular maker. I have found varying angles in the different sizes of the same make. In the plane described I have insisted on uniformity in this matter. This instrument has been in continuous use at the Queen's Hospital for over eighteen months, and even those attempting the operation for the first time rarely fail to clear the adenoids out of the rhinopharynx in one sweep.

Sharpness of the Blade

This is a matter of supreme importance. As the adenoid mass is shaved off, and not curetted, it follows that the blade must be razor-sharp. Actually the metal of the instrument is not an ideal medium to take and retain such an edge. The metal of the blade is in one piece with the rest, and therefore cannot be tempered highly lest the whole should become too brittle. If, however, the edge is set very frequently it will serve its purpose well. The surgeon can do this for himself with a small oilstone. A blunt or jagged edge is liable to tear into and strip the mucous membrane. Copious and often prolonged bleeding occurs when the pharyngeal venous plexus and branches of the ascending artery are involved. If, in addition, excessive force is used, fibres of the superior constrictor muscle may be detached. Unsightly scars and tags, occasionally followed by post-nasal dryness, are then to be expected. Messrs. Allen and Hanbury have made a plane to my design (Fig. 4) where the blades are

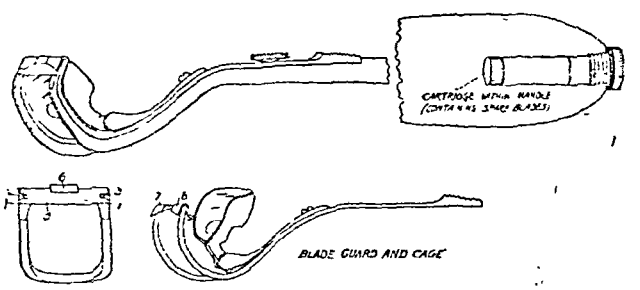

FIG. 4.—The author's adenoid plane with removable blades. The figures indicate points of support for the blade.

removable and interchangeable, with six spares carried in the handle. These blades are cut-down commercial safety razor blades, which, being spring steel of correct temper, have a superb cutting edge, and make this an ideal instrument to use. The safety cage is so designed as to hold the blade on both surfaces and all four sides—nine points in all—and is therefore absolutely secure. The spare blades are naturally inexpensive. One can always be certain of a razor edge and a clean operation.

Anaesthetic

It cannot be stressed too strongly that a deep anaesthesia is not only unnecessary, but undesirable; it should be on the light side, and the coughing reflex must have returned before the operation is commenced. The tonsils are usually enucleated beforehand by guillotine or dissection, where anaesthesia must be sufficiently deep to relax completely the musculature of the throat. One can safely wait until the anterior and posterior pillars and soft palate begin to contract, as one is operating behind them and against a firm base. If the bloodless method of enucleation is employed, as described in my paper (*British Medical Journal*, 1929, i, 988), the operative field is clear of blood and the moment of the returning reflexes is immediately seen. Where swabs are being pressed into the throat the commencement of retching and gagging indicates the moment to commence adenectomy. Only where the surgeon intends to control the immediate haemorrhage by pressure is deeper anaesthesia permissible, when, as soon as the adenoids are removed, the palate is retracted forwards and the post-nasal space is packed with gauze wrung out in sterile liquid paraffin and moistened with ferric chloride solution. This packing is left in for approximately two minutes. When the packing has been removed the soft palate is again pulled forward, and the rhinopharynx can be inspected.

The Operation

With regard to the position of the patient, the important thing is that the head must be at a lower level than the larynx to avoid the aspiration of blood. The following are the stages of the operation (Fig. 5):

1. The post-nasal space is carefully examined with the finger to determine the size of the mass and extensions. Under good illumination the instrument is inserted behind the soft palate and pushed upwards until it touches the vault.

2. The handle is dropped towards the chest, so that the back of the cage rests against the posterior edge of the nasal

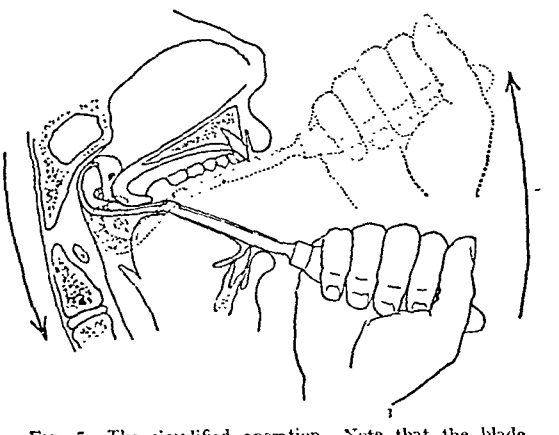

FIG. 5.—The simplified operation. Note that the blade "hugs" the post-nasal wall at every stage. (Drawn to scale.)

3. Applying moderate pressure, the blade is swept down septum and the blade engages the upper portion of the adenoid mass in the vault.

the post-nasal wall by raising the handle towards the face.

4. When the cage appears from behind the palate it is swept out of the mouth. This detaches the adenoids, and the whole mass will be found in the cage. The movements are, of course, continuous.

The operator must keep strictly in the mid-line or long axis of the body. There is then no risk of injury to the Eustachian cushions. Never more than moderate pressure is required if the blade is keen. I have seen shavings from the body of the atlas where the operator has been too heroic. This did not seem to be followed by anything worse than a transient feeling of stiffness in the neck. The adenoid mass occasionally extends laterally into the fossae of Rosenmüller. This is ascertained beforehand by palpation. I have found that most of it can be coaxed into a more central position by breaking down adhesions with the finger, and then removing them together with the central mass. I am indebted to Sir James Dundas-Grant for this hint. Where this is ineffective these extensions must be removed by carefully inserting the instrument to one or other side of the mid-line behind each Eustachian cushion, and proceeding as before. The bleeding is usually brisk and of short duration, ceasing spontaneously. Where it appears to be excessive, a blunt instrument, combined with too much force, is usually to blame, and packing may be necessary.

THE CHOICE OF A BLOOD SUGAR METHOD FOR CLINICAL WORK

BY

FREDA K. HERBERT, M.A., M.B., B.S.*
BIOCHEMIST, ROYAL VICTORIA INFIRMARY, NEWCASTLE
AND
MARGHERITA C. BOURNE, B.A., M.Sc., PH.D.
(From the Department of Chemical Pathology, St. Bartholomew's Hospital)

Modern methods of blood sugar determination are numerous, and the choice of one has usually been regarded as a matter merely of personal predilection. The purpose of this paper is to emphasize two principles which are of importance in the choice of method as they concern the validity of the results obtained. The first is the use of a procedure which gives a true sugar figure, unaffected by the non-sugar-reducing material of blood; the second is the use of capillary blood, since the capillary sugar figure is the same as the arterial figure, whereas the venous figure is, under certain conditions, much lower.

TRUE SUGAR

The criteria by which a method is ordinarily judged are: (1) that it must give accurate results on pure glucose solutions; (2) that it must give constant results when multiple analyses are made on one blood sample; and (3) that it must recover quantitatively glucose added to blood. These are minimum requirements, which are fulfilled by all the recognized blood sugar methods. But these criteria leave untouched the question of whether all the reducing substance contributing to the "sugar" figure of a blood sample is glucose. There is, in fact, non-sugar material present in corpuscles which has different effects in different analytical methods, so that the figure obtained for a given blood sample depends on the analytical method used.

Some of the methods of protein precipitation used in blood sugar determination allow the non-sugar-reducing substance to reach the filtrate, whereas in others the non-sugar material is precipitated (or retained in corpuscles) so that the filtrate contains no reducing substance other than glucose. Moreover, the various oxidizing reagents (copper or ferricyanide solutions) used in sugar determinations are differently affected by the non-sugar material. It is necessary, therefore, to consider the behaviour of the non-sugar material, both at the protein-precipitation stage and in the subsequent analysis of the filtrate. Methods of determining the true sugar depend on avoiding the effect of the non-sugar fraction, either by using a method of protein precipitation which eliminates it or by using a copper reagent which is not reduced by it. The methods of protein precipitation of Somogyi, of Herbert and Bourne, and of Folin (1930) yield filtrates containing only true sugar, so that any analytical method used with these filtrates gives a true sugar figure. The Benedict method (1928) depends on the opposite principle—the copper reagent is unaffected by the non-sugar-reducing material, and the method therefore gives true sugar figures, whatever the method of protein precipitation. It was described for use with the Folin-Wu filtrate, which contains the non-sugar material. The reducing effects of the non-glucose material of human blood may be entirely explained as due to the glutathione, which is present only in corpuscles, and of which there is probably 40 to 60 mg. per 100 c.cm. normal whole blood.

In Table I are summarized the average effects produced, for normal human blood, when various analytical procedures are used in association with various precipitation methods. The figures give the non-sugar fraction in terms of glucose (mg. per 100 c.cm.).

TABLE I

Methods of Precipitation of Protein	Methods of Analysis of Filtrate: Hagedorn-Jensen	Shaffer-Hartmann (Somogyi's Modification)	Folin-Wu	Benedict (1928)	MacLean
Tungstic acid precipitation of haemolysed blood (Folin-Wu)	28	25*	11*	0*	Definite but variable
Tungstic acid precipitation of non-haemolysed blood (Herbert and Bourne)	0	0	0	0	—
Zinc hydroxide precipitation at *p*H 7.4 (Somogyi)	0	0	0	0	—
Zinc hydroxide precipitation at *p*H 6.8 (Hagedorn-Jensen)	4*	—	—	—	—
Ferric hydroxide precipitation (MacLean)	—	—	—	—	Probably none

The asterisks show the combinations in the methods as originally described.

From the above table it is evident that some of the recognized methods are influenced by the non-sugar material sufficiently to affect the interpretation of results in clinical work. In the Shaffer-Hartmann method the Folin-Wu precipitation, which allows the non-sugar material to pass into the filtrate, is associated with an analytical method which is affected by this non-sugar fraction, and the resulting error is about 20 mg. per 100 c.cm. The same criticism applies to the original Folin-Wu method, but the error is here only about 11 mg. per 100 c.cm. In the original Hagedorn-Jensen method, the protein precipitation allows only a fraction of the non-sugar material to pass, and this method is therefore subject only to small errors, although the ferricyanide reduction is greatly affected by the non-sugar material, as is shown by the results of combining the ferricyanide reduction with the Folin-Wu precipitation. In the original MacLean method the effect of the non-sugar fraction is most probably negligible, owing to the use of the ferric hydroxide precipitation; but the evidence for regarding MacLean's method as giving true sugar figures is less complete than in the case of the other methods which estimate true sugar. The figures here given refer to normal human blood. Since the interfering substance is a constituent of corpuscles, its amount depends upon the corpuscle content of the blood. In anaemia the concentration of non-sugar substance in whole blood is therefore reduced, whereas in polycythaemia it is increased.

The two protein precipitation methods which yield true sugar figures and to which several analytical methods are applicable are (1) the zinc hydroxide precipitation of Somogyi, and (2) the tungstic acid precipitation of non-haemolysed blood, described independently by Herbert and Bourne and by Folin. Folin now recommends the latter method instead of the original Folin-Wu technique for the Folin-Wu system of blood analysis. Its special importance is in determinations of sugar and of uric acid. The technique used by Herbert and Bourne for venous blood is as follows: 1 c.cm. of blood is suspended in 8 c.cm. 3 per cent. sodium sulphate (Na_2SO_4, $10H_2O$); 0.5 c.cm. 10 per cent. sodium tungstate (Na_2WO_4, $2H_2O$), and 0.5 c.cm. 2/3 N. sulphuric acid are added. The reagents are mixed without undue shaking, and the mixture is filtered or centrifuged. There should be no unnecessary delay in the separation of the filtrate when once the tungstate and acid have been added. In this method the glutathione remains within the corpuscles, whereas

* Working with a grant from the Medical Research Council.

the glucose freely diffuses through the mixture, so that the filtrate contains the same amount of glucose as a Folin-Wu filtrate, but no glutathione. The corpuscle proteins are not precipitated, and the corpuscles are mechanically removed with the plasma protein precipitate.

THE USE OF CAPILLARY BLOOD

Foster has shown that, in the dog, the blood from a prick in the paw has the same sugar content as the blood from the femoral artery, whereas the blood from the femoral vein contains less sugar. That is to say, the blood loses no measurable amount of sugar in its passage through the skin, whereas venous blood which has passed through muscle tissue has been depleted of sugar since it left the arteries. For human subjects also there are important differences between the figures obtained on blood taken by capillary puncture of the ear or finger and on venous blood from an arm vein. These differences are most marked during insulin action. The difference is therefore small in the normal fasting subject and in the untreated diabetic, but it becomes noticeable in the diabetic under insulin. It is very marked in non-diabetic subjects after administration of glucose, when the blood sugar is beginning to fall under the influence of the individual's "endogenous" insulin secretion. At this period of a sugar tolerance curve it is usual to find the venous figure lower than the capillary figure by 40 to 80 mg. per 100 c.cm.

THE SIGNIFICANCE OF THE CHOICE OF METHOD FOR THE CLINICAL INTERPRETATION OF RESULTS

In view of the difference between capillary and venous blood it is very important to use a method applicable to capillary blood for the differentiation between renal glycosuria and hyperglycaemic glycosuria. The renal threshold is, strictly speaking, that concentration of sugar in the renal artery at which the kidney begins to excrete glucose. The cutaneous capillary sugar is an index of the sugar content of the general arterial system, and is therefore the best available approximation to the figure for renal arterial blood. If the venous blood sugar curve is taken instead of the capillary, the renal threshold may be placed too low by 40 to 80 mg. per 100 c.cm. This is the type of work for which a capillary method is essential; for other work it is desirable, but not so necessary. In work on proved diabetics the use of a method requiring venous blood will scarcely cause serious error.

The errors due to the use of methods which do not give true sugar figures are great enough to be of some clinical importance. They are evidently large enough to be of clinical interest in the Shaffer-Hartmann method and in the ferricyanide method applied to Folin-Wu filtrates; but as these methods are not much used in this country it is not necessary to consider them in detail. The only method commonly used for routine work which is liable to errors of any importance is the Folin-Wu method, which, for blood of normal corpuscle content, gives figures too high by 9 to 16 mg. per 100 c.cm. whole blood. Such differences are of slight importance when the blood sugar is high, but they may be of importance when the sugar is low, for the non-sugar fraction remains the same, while the glucose changes. If, for example, the true sugar is 60 mg. per 100 c.cm. and the apparent sugar 76 mg. per 100 c.cm., the difference is great enough to cause a hypoglycaemia to be regarded as normal. Since carbohydrate metabolism is now being studied in many non-diabetic conditions, and, in particular, since chronic hypoglycaemia is regarded as a definite clinical syndrome, it is important that true sugar figures should be obtained. This is likely to be of special significance in the study of children's diseases, since children are prone to dehydration, and the relative rise in corpuscle content in anhydraemia will cause a proportionate increase in the non-sugar effect. We have seen an infant double its red cell count and haemoglobin as a result of dehydration. Under such conditions one would expect the Folin-Wu figure to be 18 to 32 mg. per 100 c.cm. above the true sugar—an error of very great importance if there is a question of hypoglycaemia.

Much work on carbohydrate metabolism in non-diabetic conditions is of very doubtful significance, owing to the differences in method and differences between capillary and venous blood. Commonly the figures are reported without any note on these points. The subject would be clarified if a true sugar method applicable to capillary blood were generally adopted. All the methods of protein precipitation mentioned in the table may be adapted for capillary blood, and there are therefore several possible combinations. As an example, the application of the Folin-Wu analysis to the tungstic acid precipitation of non-haemolysed blood is given below.

Micro-Method for the Determination of True Sugar by a Modified Folin-Wu Method

Reagents.—1. 3 per cent. sodium sulphate (Na_2SO_4, $10H_2O$).
2. 10 per cent. sodium tungstate (Na_2WO_4, $2H_2O$).*
3. 2/3 N. sulphuric acid.*
4. Folin-Wu copper reagent.*
5. Phosphomolybdic acid reagent.*
6. Standard glucose solution (a stock solution of 1 per cent. glucose in benzoic acid is diluted to 0.01 per cent. for use).

* As in the original Folin-Wu method.

Protein Precipitation.—Take 3.6 c.cm. sodium sulphate solution, and measure into it 0.2 c.cm. blood. Add 0.1 c.cm. tungstate solution and 0.1 c.cm. 2/3 N. sulphuric acid. Mix the reagents without undue shaking, and separate the fluid at once by centrifuging and pouring the supernatant fluid through a small filter (filter paper, Whatman No. 41, 5.5 c.mm.). It is possible to obtain just over 2 c.cm. of filtrate, provided the filter is of the size mentioned.

Analysis.—In three Folin's tubes (graduated at 12.5 c.cm. and 25 c.cm), A, B, and C, take:

A. 2 c.cm. filtrate,
2 c.cm. Folin-Wu copper solution.

B. 1 c.cm. 0.01 per cent. glucose (that is, 0.1 mg. glucose),
1 c.cm. water,
2 c.cm. Folin-Wu copper solution.

C. 2 c.cm. 0.01 per cent. glucose (that is, 0.2 mg. glucose),
2 c.cm. Folin-Wu copper solution.

B and C are the standards.

Mix the contents of the tubes, and place them in a boiling water bath for six minutes. Cool for one or two minutes, without shaking. To each tube add 2 c.cm. phosphomolybdic acid solution. Dilute to the 12.5 c.cm. mark with water, and mix thoroughly. Compare the unknown A in the colorimeter with the standard either B or C, whichever is closer to it in colour.

Calculation.—In the protein precipitation 0.2 c.cm. blood was diluted to a total volume of 4 c.cm. Of the filtrate 2 c.cm. were taken—that is, a volume equivalent to 0.1 c.cm. blood. Let S be the reading of the standard, U the reading of the unknown, and x be mg. glucose in the 2 c.cm. filtrate taken. Standard B contains 1 c.cm. of 0.01 per cent. glucose—that is, 0.1 mg. glucose.

$$x \times U = 0.1 \times S$$

$$x = \frac{0.1 \times S}{U}$$

$\therefore$ 2 c.cm. filtrate contain $\frac{0.1 \times S}{U}$ mg. glucose

$\therefore$ 0.1 c.cm. blood contains $\frac{0.1 \times S}{U}$ mg. glucose

$\therefore$ 100 c.cm. blood contain $\frac{0.1 \times S \times 100}{0.1 \times U} = \frac{S}{U} \times 100$

Similarly, for the standard C the blood sugar is $\frac{S}{U} \times 200$.

Memoranda

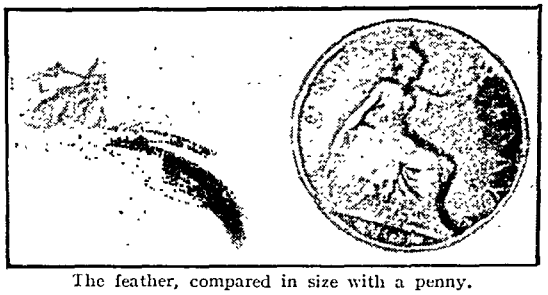
MEDICAL, SURGICAL, OBSTETRICAL

FOREIGN BODY IN THE NECK

THE following case deserves record if only because of its resemblance to one of the cases mentioned in an annotation on the extrusion of inhaled foreign bodies published in the *British Medical Journal* of February 1st, 1930 (p. 210).

A female breast-fed child, aged 9 months, was brought to hospital with the history that four days previously a small swelling was noticed on the right side of the neck below the jaw. The family doctor that day had diagnosed "sore throat."

On examination the throat was red, and both hypertrophied tonsils were inflamed, especially the right one, which



The feather, compared in size with a penny.

was surrounded by a considerable amount of sticky muco-pus. A small tender swelling was present just below the middle of the right ramus of the mandible. This swelling rapidly diffused and increased, the overlying skin becoming red and oedematous, and six days after the first appearance of the "lump" a skin incision was made over its fluctuant centre, allowing extremely foul pus to escape (*B. coli*).

The abscess cavity was enlarged by sinus forceps, and a foreign body, which proved to be a contour feather 1½ inches long, protruded from the wound. The proximal or quill end was fairly rigid and quite sharp. The wound is now healing rapidly.

On inquiry, the mother admitted that about a week before any swelling was noticed, her 7 years old daughter told her that "the baby had swallowed a feather from the pram eiderdown." I might add that this baby, when 5 months old, was operated on in this hospital for intussusception.

A. J. P. ALEXANDER,
House-surgeon, Belfast Hospital for Sick Children.

ACUTE PUERPERAL INVERSION

The following details of a case of acute puerperal inversion may be of general interest, following the report of Dr. Noel Hypher, which appeared in the *Journal* of August 2nd, 1930 (p. 179). This is the second case of the kind which I have seen in the past five years.

A married woman, aged 34, had had three previous labours. The first, in 1918, was normal, apart from the placenta being adherent and requiring manual removal which was associated with haemorrhage. The second labour, in 1922, was complicated by a breech presentation, the child being stillborn. An adherent placenta came away one and a half hours later, with haemorrhage. The third labour was also concerned with a breech case; the child lived for twelve hours, and the placenta was again adherent. There was no history of abortion or irregular menstruation in the intervals between the labours.

I was called to see this patient on March 16th, 1930, and found the os fully dilated and a breech presentation. I delivered a full-time child, who breathed and cried lustily after some time. I waited one and a half hours for the delivery of the placenta. The patient had lost a fair amount of blood, and the haemorrhage was becoming increasingly profuse, so I decided to remove the placenta manually. It proved to be calcified in parts and very adherent, but I extracted it piecemeal; during the manipulation I felt what I took to be a tumour about the size of a hen's egg, and not truly pedunculated. The patient was much collapsed and suffered from shock; her pulse was 128 and its tension was weak. Her respirations were of the sighing type, and she was cold, clammy, and sweating. A hypodermic injection of strychnine and pituitrin was given, and the patient was immediately removed to hospital by ambulance, where her pulse improved steadily as the result of the application of warmth, four-hourly injections of strophanthin, and rectal injections of glucose and saline solution.

At 6.30 p.m. on March 20th complete inversion of the uterus occurred while a bedpan was being used. A fibromyoma was found attached to the inside of the fundus; replacement proved impossible, and amputation became necessary. I tied a tourniquet as high up as I could, made a vertical incision through to the serous coat, and established the absence of any prolapse of the bowel or bladder. I then continued the incision round the level of the lower os, stripped the peritoneum, and repaired it. I oversewed the uterine stump with interrupted sutures and a continuous suture. The tourniquet was then removed and the stump replaced. The patient made a good recovery and left hospital after five weeks.

The interesting points of this case are the question whether there is any relation of an adherent placenta to intrauterine tumours; the absence of symptoms relating to the tumour; the three successive breech births; and the placenta being found adherent at each delivery.

I wish to thank Dr. Stewart for his kind assistance and interest in the case.

Krugersdorp. LAURENCE D. ADLER, M.B., Ch.B.

POISONING BY CAMPHORATED OIL

Although the occurrence of cerebral symptoms following poisoning with camphor is well known, I think the following case might be of general interest owing to its very definite symptoms.

A girl, aged 10, who is a mild grade mental deficient, while at home on leave from an institution, was admitted to the casualty department of Walsall Hospital with a history of having taken by mouth twopennyworth of camphorated oil (about 75 grains of camphor) one and a half hours previously, followed by "a fit." On examination the child was pale and drowsy; the temperature was 99° F., the pulse 105, and the respiration 30; she was able to answer questions clearly.

The stomach was washed out, and a considerable quantity of camphor-smelling oil was removed; several ounces of concentrated magnesium sulphate were left in the stomach, and the child was admitted to hospital. The next morning she

was very drowsy, but could be awakened. The temperature was then normal, but by 4 p.m. had risen to 101°, the pulse being 148 and the respiration 36; by 8 p.m. the temperature had reached 104°. The child complained of pain over the lumbar region and the left hip. There was no bowel action.

On the second day the temperature rose to 105.6° at 10 a.m.; there was headache, and the pain over the left hip continued; the abdomen was soft, there was no tenderness, and the chest was normal. The throat was slightly inflamed. The child was still very drowsy, and an enema produced only a slight constipated result. The condition remained practically unchanged throughout the day.

On the third day the temperature was 105.4°, the pulse being 152 and the respiration 40. The child was very drowsy and lay curled up on her side. She complained of severe headache, and of pain at the back of the neck, in the shoulders, and in the dorsal region. She was uttering constant slight cries, and definite head retraction was present. The pupils were unequal, but reacted to light; the ocular movements were normal, and there was no nystagmus nor other cranial nerve disturbance. All the limb and abdomen reflexes appeared hypersensitive, but the Babinski sign was absent. Pronounced ankle clonus was obtainable on both sides, and Kernig's sign was strongly marked. The arms were maintained in a flexed position with moderate rigidity. Lumbar puncture was performed at 3 p.m., and 22 c.cm. of clear colourless fluid, under pressure, were withdrawn. The report showed a cell percentage of less than 1; globulin was not in excess, the protein percentage was 50 mg., that of chlorides 0.71, and of sugar 0.118. By 6 p.m. the temperature had dropped to 102°, and the child was much less restless. Four hours later it was 98.4°, the pulse rate being 130 and the respiration rate 30; she was sleeping quietly.

On the fourth day the child appeared very much better, the temperature being 97.2°, the pulse 118, and the respiration 24. The pupils were now equal, but the muscles generally were still very irritable. Kernig's sign was still present but not marked. She was not drowsy, and was very hungry. The child had her first unaided bowel action with a semi-fluid and dark greenish result. On the fifth day the temperature was 97.4°, the pulse 72, and the respiration 22. The child appeared perfectly normal, and her appetite was good. On the eleventh day there was a rise of temperature to 101.4°, without symptoms, and the child was discharged cured on the sixteenth day.

I am indebted to Dr. Frank Layton, senior physician to the Walsall General Hospital, for permission to publish this case.

Senior House-Surgeon, Walsall General Hospital.

EXTRAUTERINE PREGNANCY OF FOURTEEN MONTHS' DURATION

The following case of extrauterine pregnancy is of interest in view of its long duration, the complications that ensued, and the recovery of the mother.

A Burmese woman, aged 36, was admitted to hospital on November 22nd, 1929, with a large abdominal swelling. The patient stated that it had been first noticed in the right lower quadrant of the abdomen about fourteen months previously, and since the menses had stopped, she thought she was pregnant. No attacks of pain or bleeding from the vagina about the third or fourth month were remembered, but foetal movements were felt about the fifth or sixth month. At ten months there was vaginal bleeding for about three days without labour pains.

The patient was a thin, ill-nourished woman, with a protuberant abdomen. The uterus was small, hard, and drawn to the left; the cervix was hard and thick, and the right fornix felt full. There was a tense and fluctuating abdominal tumour, dull to percussion in all positions, and extending from the xiphoid cartilage downwards, involving the entire abdomen. A fluid thrill was present, but there were no enlarged veins coursing over the abdominal wall. A solid tumour was indistinctly felt on deep pressure. A cyst of the right ovary was provisionally diagnosed, and the patient was prepared for operation.

On December 9th she was anaesthetized with chloroform, and a median incision was made below the umbilicus. The peritoneum was hardly recognizable, being thick and covered with blood vessels. On opening it a large quantity of brownish fluid escaped and a white mass was presented, which on examination proved to be the thigh of a child. The head was near the xiphoid, and the breech below the level of the umbilicus of the mother. The body was that of a dead full-grown female child, with a thick umbilical cord. There was a large placenta attached to a thin sac in the abdominal cavity, from which it was separated by adhesions, some coils of intestine being adherent to the sac. The child was covered with a greenish-yellow deposit, and the flesh was quite firm, except that the hair on the head came off on the slightest pressure. When the child was delivered the placenta was found to be adherent; it had to be very carefully removed for fear of breaking down the adhesions and infecting the general peritoneal cavity. Since the placental circulation had presumably stopped some days previously, the placenta was soft and had to be carefully scraped out. No attempt was made to remove the sac, as it would certainly have resulted in the infection of the peritoneal cavity, but it was scraped and washed, and the walls were approximated by catgut sutures, the abdomen being closed in the usual way. No opening was detected connecting the sac with the uterus or Fallopian tubes.

On the third day after operation there was an evening rise of temperature to 100° F.; the pyrexia persisted for the next three days, when the patient had a profuse foul-smelling discharge from the vagina. The temperature then fell to normal, where it remained. The discharge continued, but diminished daily. The abdominal stitches were removed on December 19th, ten days after the operation, and the wound healed by first intention. On December 22nd a little serous discharge emerged from one of the stitch holes, and on the following day discharge resembling that from the vagina appeared at that hole. Evidently the sac walls had not united and the discharge from it was finding vent through the abdomen and vagina. A drainage tube at the outset might perhaps have prevented this complication. By January 28th, 1930, all discharge had stopped, and the abdominal sinus had completely healed, the patient leaving the hospital quite well on February 18th.

Civil Surgeon, Sagaing, Burma.

Reports of Societies

ETIOLOGY OF DISSEMINATED SCLEROSIS

At a meeting of the Section of Neurology of the Royal Society of Medicine, on January 8th, with Mr. LESLIE PATON in the chair, a paper on chronic subdural haematoma was read by Dr. J. PURDON MARTIN.

Dr. Martin said that cases of chronic subdural haematoma were nearly always associated with a history of injury. The bleeding probably came from small vessels of the dura torn by the blow; the blood remained fluid, possibly owing to its defibrination by transmitted pulsation from the brain. In 40 per cent. of cases the haematoma was bilateral. A vascular, fibrous membrane enclosed the fluid, which Virchow thought was formed by the organization of inflammatory exudate. In the early stages there were few symptoms, and signs of local pressure were absent until late. Dr. Martin did not consider that trauma was the only etiological factor, especially in patients over 40. Degeneration of the arteries or alcoholism might have a considerable influence. The latent period following trauma might last three or four months or even a year. The symptoms included drowsiness, headache, ocular disturbances, and sometimes mental changes; focal symptoms might develop in the late stages. The treatment of election was operation with evacuation of the contents of the haematoma, and recovery was usually complete.

Dr. C. P. SYMONDS said that as diagnosis was difficult in these cases operation should be undertaken whenever a suspicion of subdural haematoma arose. The injury which was responsible was often described as trivial, and the latent period was frequently long.

Dr. E. ARNOLD CARMICHAEL, opening a discussion on the etiology of disseminated sclerosis, with special reference to spherula insularis, said that claims had recently been made by workers at the Westminster Hospital that spherula insularis could be cultured from the cerebro-spinal fluid of patients with disseminated sclerosis. In the first place, in conjunction with Dr. Greenfield, he had tried to reproduce their results with the Langer gold salt tests. The gold solution was made by the method of Mellanby and Davis, which he believed to be more reliable than that employed at the Westminster Hospital, where, he thought, too sensitive a solution might have been used, as his results were indefinite and not in agreement with those of the workers there. Secondly, it had been found at Westminster that, following the ingestion of 50 grams of levulose, the proportion of levulose in the blood rose above the normal limit of 30 mg. per 100 c.cm. in a large number of cases. In his series this limit had been exceeded only in six patients, one of whom had recently been confined, while in twenty-two it remained below normal limits. He thought that a less pure form of levulose, or the previous exhibition of arsenic, might be responsible for the Westminster results. Thirdly, he had repeated the experiments on the *p*H values of cerebro-spinal fluid, serum, and broth mixtures. Since the bubbling hydrogen electrode used at Westminster caused excessive frothing of the solution and drying of the platinum he had chosen a closed cell method. Hartley's broth was employed, and the serum was obtained from hospital students; he had found it difficult to obtain a mixture of *p*H 7.6 or 7.5, as was said to be necessary. In every case he found that the *p*H of the mixture rose to the alkaline side during the days which followed; on no occasion had he observed the shift to the acid side described by the Westminster workers. An alkaline change was inevitable under aerobic conditions owing to the escape of CO_2 from the mixture; by keeping the mixture under paraffin he had found that the *p*H was still raised, though more gradually. Finally, of eight cultures from the cerebro-spinal fluid of patients examined at Hampstead, and of eleven examined at Queen Square, no spherules had been found. Among thirty-two samples cultured independently at Queen Square and at Westminster, no spherules had been seen in fourteen from patients with disseminated sclerosis and in seventeen with other conditions, but spherules had been grown at Westminster from the cerebro-spinal fluid of a chorea patient.

Sir JAMES PURVES-STEWART thought the apparent variations of Dr. Carmichael's results from those of Westminster were due to the use of different methods. It had never been claimed that a positive result in the gold curve indicated the presence of a living virus; it was probably an effect of the toxin of some causal agent. In a similar way the levulose tolerance test was only of value as an indication of deficiency of the liver as the result of injury by toxins, and had no importance unless associated with indican in the urine and positive glycuronic tests. Workers in England and in Budapest had confirmed Miss Chevassut's work, and three groups of observers, therefore, had reached the same conclusions, as opposed to one dissentient.

Miss CHEVASSUT said she believed that the method of preparation of the gold salt laid down by Langer and used at the Westminster Hospital gave reliable results. Dr. Carmichael had used a different method, and in his results had given no details of the points at which the colour changes occurred. His findings were therefore scarcely comparable. The levulose given at Westminster had been identical with that used by Dr. Carmichael. In the experiments on *p*H values he had been attempting to measure the reactions of cultures without knowing whether a culture was present or not. If, with her method, he had found nothing to be excessive, his technique was faulty; that method had been chosen because it had the advantage of removing free CO_2, and hence it avoided the alkaline change due to loss of CO_2 which he had observed. His suggestion that paraffin should be used to prevent this change defeated the end in view, since an attempt was being made to culture the virus aerobically. The acid change was slight, and, by using Dr. Carmichael's method, might easily be masked by the alkaline change. With regard to microscopical examination, the technique was difficult; results were usually obtained only after two or three examinations of the same case.

Mr. J. R. MARRACK said that it was quite impossible to wash out the CO_2 from the mixture by Miss Chevassut's method in any reasonable time. With a *p*H of 7.5 a third of the CO_2 present would be free, and as long as any CO_2 remained in the mixture that proportion of it would be liberated.

Mr. J. E. BARNARD said that in the eight cultures which he had examined at Queen Square he had failed to find anything abnormal. Among the small proportion of Miss Chevassut's cases seen by him, he had certainly observed something which was new to him. Whether this finding was distinctive of her cases he did not know.

Miss A. R. KERRIDGE said that, as far as she could see, Dr. Carmichael's electrode should give results more relative than those of Miss Chevassut. But the errors appeared to go the wrong way; with Miss Chevassut's technique one would expect the mixture to become more alkaline. Dr. Carmichael's results did not explain why Miss Chevassut found an acid change.

Dr. J. G. GREENFIELD preferred the method of Mellanby and Davis for the preparation of the gold salt solution; he had come to the conclusion many years ago that the formalin method was not reliable. He had found normal gold curves in untreated cases, and in cases within a month of death.

Dr. CARMICHAEL, in his reply, said that he left his figures and those of Miss Chevassut to the judgement of the meeting. It had been suggested that he should repeat his observations, and if Miss Chevassut would advise him in employing her technique he would welcome her help.

EDINBURGH OBSTETRICAL SOCIETY

At a meeting of the Edinburgh Obstetrical Society held on December 10th, 1930, with the president, Dr. H. S. DAVIDSON, in the chair, Dr. JAMES DAVIDSON read a paper on the histological changes occurring in the liver in a series of cases of eclampsia, with reference to the clinical manifestations, in which a series of cases was discussed, both with regard to the clinical manifestations and to the pathological changes occurring in the liver and kidneys.

It was shown that there were at least three different types of lesion found in the liver—namely, necrosis of the cells of the peripheral zones of the lobules; widespread necrosis of the cells in the central and mid-zones; and small areas of focal necrosis with no gross hepatic lesions. These pathological changes were found in cases which clinically were typical of eclampsia, in cases with fits and low blood pressure, in those with no fits and high blood pressure, and in those with no fits and low blood pressure. In other words, cases diagnosed clinically either as eclampsia or as a severe toxaemia of pregnancy were shown to have the same pathological lesions. The striking resemblance of the more severe type of liver lesion to acute yellow atrophy was discussed, and the severity of

the renal changes was contrasted with those found in the liver. It was suggested that the kidney lesions were to a certain extent secondary to the hepatic condition.

Dr. R. EVERETT reported on a case of traumatic rupture of the uterus at the fourth month. The patient, aged 18, was thrown off the pillion of a motor cycle going at thirty miles an hour. She was admitted to hospital in a dazed condition, and for several days suffered from cerebral irritation associated with a moderate degree of shock and a pulse of 130. She had also a Colles's fracture of the left forearm. She gave a history of having missed four periods. There were apparently no abdominal symptoms. For seven weeks after the accident she had a slight vaginal discharge, when she was readmitted to a gynaecological ward. She was then found to have a hard mass in the right iliac fossa, which was thought to be a haematoma of the abdominal wall that had undergone some calcification. Curettage was performed, and a few fragments of what appeared to be retained placenta were removed. The patient was discharged a week later, having had an uninterrupted convalescence with no further bleeding. Three weeks later she reported at hospital and stated that she was feeling well and had returned to work two days previously. The mass on the right side appeared to be harder, and an *x*-ray photograph was taken which revealed a lithopaedion. A lipiodol examination was carried out, when it was found that the lithopaedion was separated from the uterus and was outside the tubes, suggestive of a rupture of the uterus. Subsequently, the lithopaedion was removed with some difficulty, as there were numerous adhesions both to it and to the uterus. The patient was discharged from hospital three weeks after operation, and two months later her periods were regular, the uterus being mobile and completely involuted.

PUERPERAL SEPSIS

At the last meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland Dr. A. H. DAVIDSON read, as his presidential address, some notes on puerperal sepsis, dealing chiefly with treatment as carried out to-day in the various large centres of Great Britain and Ireland. Some recent work on the bacteriophage of the genital tract before and after labour suggested that the commonest type of severe puerperal sepsis, that due to haemolytic streptococci, was always an exogenous infection. Non-haemolytic streptococci were constantly present in the vaginal flora; under conditions of lowered resistance they became virulent and gave rise to an endogenous infection. Attention had recently been drawn to anaerobic streptococci as a cause of puerperal sepsis. Albuminuria, haemorrhage, anaemia, and laceration or bruising of the soft parts were predisposing factors which also were of great importance. Vaginal examinations and intrauterine manipulations should be avoided as far as possible. Many deaths from sepsis followed manual removal of the placenta, an operation sometimes rendered necessary by unskilled conduct of the third stage of labour. In considering treatment Dr. Davidson laid stress on the importance of prophylaxis by keeping the patient in good condition throughout pregnancy and labour. When sepsis had developed, good nursing and the relief of any distressing symptom were of much value. Drainage of the uterus by postural treatment was essential, and the patient should be made to sit upright in bed for short periods five or six times daily. Intrauterine douching or exploration should be carried out only when it was reasonably certain that something had been left behind. Rheinstaedter's curette should never be used in a septic uterus. Hysterectomy and ligation of the pelvic veins had a small place in the treatment of uterine sepsis, but the results were not very encouraging. There were also such forms of treatment as Hobbs's glycerin method, the giving of vaccines and serums, intravenous injection of antiseptic solutions such as collosol iodine, mercurochrome, eusol, and the arsenobenzol preparations, and Luker's serum and quinine technique. All these methods had their successes, but none was a specific.

Sir WILLIAM SMYLY said that the chief impression left on his mind by the President's paper was that "meddlesome midwifery was bad." At present the first duty of doctors in connexion with puerperal sepsis seemed to be that of prevention. Dr. T. M. HEALY thought that in dealing with cases of sepsis nursing did more to help the patient's recovery than any drugs known at present. He felt that the value of drugs in these cases was exaggerated, and that the chief essentials were plenty of sleep and plenty of nourishment. In the war immuno-transfusion had been proved to be of little use.

Dr. G. FITZGIBBON gave an outline of the views he had formed from his own experience. It was a mistake to speak of puerperal sepsis as though the condition were a single and separate disease. He divided the cases into two distinct groups: (1) those in which, after delivery, the woman's tissues were undamaged and undevitalized; (2) those in which there had been protracted labour with prolonged devitalizing pressure on the soft parts. In the first group the infection was due to invasion by pathogenic organisms of a host in whom a pre-existing debility had lowered the normal resistance. In these cases the infection was usually exogenous, due to carriers, indirect contacts, or faulty operative technique, but in a small number quiescent dental root or tonsil infection was responsible, the organism being a streptococcus, though not necessarily haemolytic. In the second group there was the immediate influence of the labour in devitalizing tissue; the infecting organisms might be exogenous and more virulent from the start by reason of the lowered resistance, both general and local, or they might be some of the normal flora of the body—staphylococci, coli bacilli, and non-haemolytic streptococci—which were opportunists, and became infective. In the first group the course of the disease was similar to that of any acute infection, and was typical of such; the rapidity of recovery depended upon the patient's resistance. In these cases specific treatment was useless. Various methods of treatment might appear to be effective, but the main treatment was general improvement of personal resistance by good nursing, comfort, feeding, sunlight, and the avoidance of decubitus. When the disease had continued for seven to ten days, it was essential to watch for localization, and, if this occurred, to treat it according to its nature. In the second group the local condition was important from the outset. The tissue damage might be so great that nothing could be done. The condition was one of gangrene; if it could be extirpated with a healthy margin this might be effective, but a margin could seldom be obtained as the parametrium was involved, and so the result depended on whether the patient's resistance was good enough to hold out until local demarcation had taken place.

Dr. BETHEL SOLOMONS considered there was a cure for every case if the obstetrician was lucky enough to strike the correct one. He believed in certain definite principles: (1) It was wrong to preserve an attitude of watchful expectancy, because some treatments did good. (2) Intrauterine douching, digital exploration of the uterus, and curetting were proved harmful treatments. (3) There was a definite but small place for hysterectomy, which, if done at the right time, would certainly save lives which would otherwise be lost. (4) Glycerin had a very small place in treatment; it was specially useful when there was suppression of lochia. (5) To await definite localizing signs in every case would retard progress in knowledge. The fact that a patient developed pneumonia did not mean that she had not sepsis; pneumonia was often an end-result of sepsis. This affected the value of statistics about sepsis, for many cases reported as deaths from influenza or pneumonia should rank as septic death. With regard to forceps, any operation increased the risk of sepsis, but unfortunately it was often necessary to apply forceps to save infant life.

Dr. D. G. MADILL said that the report on puerperal sepsis submitted to the last London congress showed

247 cases with 87 deaths—that is, nearly 33 per cent. mortality. Of the 87 deaths, 19 had had spontaneous delivery; and 68 active intervention. Of the 160 recoveries, 42 had normal labour and 118 active intervention; sixty different methods of treatment were used. Meddlesome midwifery and unnecessary forceps delivery should be avoided if sepsis was to be prevented; training of the district nurse should be extended, and each nurse should have a short post-graduate course every few years. The one advance in active treatment was abandonment of douching and of the blunt curette. Exploration of the uterus was permissible only if a piece of placenta was known to be retained, or, in certain cases, for taking an intrauterine culture. A great many of the cases listed in the reports of maternity hospitals as normal deliveries did not deserve the term at all, because the women had been long in labour and the tissues were devitalized, and this trauma led to sepsis later on. The lines laid down for the treatment of any case of fever seemed to him to be the best for the treatment of puerperal sepsis.

Dr. R. J. ROWLETTE thought that although very little advance had been made in the treatment of puerperal sepsis in the last generation or two, ideas as to its cause were now a good deal clearer. The organism most frequently found was the *Streptococcus haemolyticus*, but there were some cases of acute sepsis due to the *Staphylococcus aureus*. These cases could not be explained as being caused by contamination during the investigation. The *Staphylococcus aureus* was not a common organism in cultures made from the circulating blood. Other organisms were often found in the uterus, such as *Bacillus coli*, but he thought it very doubtful whether *B. coli* was ever really the cause of the infection. He did not think the views put forward as to the presence of anaerobes playing an important part in the causation of sepsis had ever been substantiated. One practical advance in the treatment of puerperal sepsis was the abolition of douching, and there was every evidence that chemotherapy was injurious. In no condition of bacterial infection was there the slightest evidence that antiseptics introduced into the blood stream had any effect in combating sepsis. Satisfactory results had been obtained by the early use of autogenous vaccines, which were preferable to serums; in combination they were very successful.

Dr. G. TIERNEY said that, before any advance could be made in the treatment of septic cases by vaccines, it was necessary to estimate the powers of resistance of the patient's blood to infection, but at present no such method was available. In acute septic infection the resistance was so lowered that any stimulus such as a vaccine failed to do good—in fact, it sometimes made the patient worse; non-specific antigen was required. Dr. R. M. CORBET referred to two septic cases in which *Staphylococcus aureus* was grown from the cultures. He believed it was possible to recognize the condition clinically. Many treatments had the disadvantage that they gave the patient lasting pain; such should be discarded as not being worth while. Dr. A. J. HORNE thought the curtailment of vaginal examinations by students and midwives was very desirable. Dr. NINIAN FALKINER mentioned a case in which a long time had elapsed between the birth of the patient's baby and the onset of sepsis; the cause was a haemolytic streptococcus. It was interesting to note that serum failed; radiostoleum, S.U.P., and a vaccine after localization cleared up the condition. He thought that the importance of administering serum at once in these cases could not be overstressed.

At a meeting of the North of England Obstetrical and Gynaecological Society, held in Liverpool on December 19th, 1930, the president, Dr. JOHN W. BURNS, delivered his valedictory address entitled "Stocktaking." This was a review of the advances made in the present-day knowledge of gynaecology and obstetrics obtained by making a *précis* of the more important papers read before the society during the past thirty years. Before the address, specimens and cases were shown and described by members of the society.

Reviews

FILTERABLE VIRUSES

Although it is more than probable that the filterable or ultra-microscopic viruses do not represent a homogeneous group, in the present state of our knowledge it is convenient to consider them together. There are certain features, such as small size, the inability to devise a lifeless medium which will sustain their growth *in vitro*, and the production of inclusion bodies in the affected tissue cells, which are common to the majority, and the editors of *A System of Bacteriology* have done wisely in devoting a separate volume[1]—the seventh—to a consideration of these viruses. Incidentally although neither the term "filterable virus" nor "ultra-microscopic virus" is satisfactory, the title "virus diseases" chosen for this volume is no better, because, of course, all micro-organismal disease would rightly come under this heading. The point is not, however, of any real consequence.

The volume opens with an introductory survey by W. E. Gye and J. C. G. Ledingham which, after a brief historical sketch, passes to a consideration of the probable nature of these viruses. Both authors are evidently of the opinion that the filterable viruses represent a form of life very similar to, if not identical with, the bacteria, a view to which many workers in this field would subscribe. Loeffler and Frosch, by the way, discovered the virus of foot-and-mouth disease in 1898, not 1892. Following this is a useful chapter on cell inclusions contributed by R. J. Ludford, which is adequately illustrated. In reviewing a volume such as this comprising thirty-nine chapters, it is impossible to do more than touch on a few of its salient features. The account of virus diseases of plants by J. Henderson Smith, though necessarily brief, is good, and will be welcomed by medical readers who have not the leisure to keep in touch with the researches of plant pathologists. Similarly, the short account of insect virus diseases by R. St.J. Brooks is acceptable. The late F. R. Blaxall has contributed an excellent chapter on small-pox and a brief account of the animal pock diseases. Chapter VIII, by J. G. Greenfield, deals with acute disseminated encephalomyelitis as an independent disease and as a complication of certain virus diseases. We are well aware that a number of authorities hold that these various conditions have a common etiological agent; but until this hypothesis has been proved experimentally, it is better not to prejudge the question by presenting the group of conditions as an entity; very similar histological findings seem hardly to warrant this attitude. An interesting account of encephalitis lethargica is given by J. McIntosh, and his judicial summing-up on the question of etiology will meet with the approval of most readers. Some may question the inclusion of such diseases as pleuropneumonia of cattle and agalactia in a volume on filterable viruses, since the causal organisms of these two conditions can be cultivated in simple artificial media. Were it not for this fact these two organisms would be grouped among the filterable viruses without hesitation, and to exclude them on the ground that they can be cultivated like the bacteria would, in our opinion, be unsound. Exception might also be taken to the presence of chapters on diseases due to the *Rickettsiae* in this volume, but here again there is much to be said for the editor's policy.

The volume concludes with an admirable account of the bacteriophage by E. M. Burnet, and although it has only been possible to mention specifically a few of the articles,

---

[1] *A System of Bacteriology in Relation to Medicine.* Medical Research Council. Vol. vii. London: H.M. Stationery Office. 1930. (Pp. 509; illustrated. Single volumes, £1 1s. net; set of nine volumes, £8 8s. net.)

that does not mean that the others are of little account. Throughout, a high standard of excellence is maintained, and we have little hesitation in saying that this will probably be the most appreciated of the nine volumes which are to constitute this *System of Bacteriology*.

AN ANALYSIS OF CREATIVE MIND

In *Creative Mind*,[2] a work of rare literary merit, Professor CHARLES SPEARMAN cold-bloodedly takes the creative faculty to pieces in an attempt to find out the "springs and mechanisms" that set and keep it going. For this undertaking he makes no apology; he has no truck with the popular superstition that knowledge of how great works are created somehow or other sterilizes the mind of the creator or abates the pleasure of those who can only contemplate his creations. "If ever," he writes, "we should succeed in prying out any secrets as to how the mind achieves these creations, it will be in the hope that such a better understanding may aid us to appreciate and to create the more effectively."

Professor Spearman's first concern is to clear the ground of current doctrines, all of which he regards as unsatisfactory and rejects with a curtness that cannot but be gratifying to those who are unable to accept the psychological systems on which they are based. "Gestalt" psychology, he holds, offers an explanation of the process of appreciating a work of art but not of making it; behaviourism, far from explaining any mental activity, expunges the very term "mental" from its vocabulary; even psycho-analysis, according to Spearman, for all its preoccupation with what he calls subconscious bestiality, lends but scant help in searching out "the mental laws by which either poet or beast is able to conjure up his amazing tropes." An open field now before him, the author sets out briefly but lucidly a series of psychological laws, qualitative and quantitative, in terms of which he believes mental creativity finds a place among the basal and ultimate powers of knowing; and the rest of the book he devotes to the practical bearing of these laws on the visual arts, music, literature, and scientific and intellectual creation. The laws are simple, some indeed may suggest too simple; but the same, the author reminds us, could be said about Newton's laws of motion. The scientist aims, after all, at expressing even the most complex events in simple terms. It is not therefore on the ground that they are less complex, less mysterious, than the phenomena they are intended to explain that Professor Spearman's laws may justly be criticized. Three qualitative principles, indicating tendencies which under the influence of certain clearly defined quantitative laws become facts, are offered confidently as defining the utmost degree of creativeness to which the human mind could possibly attain; first, the principle that a person tends to know his own sensations, feelings, and strivings; secondly, that when two or more items (percepts or ideas) are given a person may perceive them to be in various ways related; and finally, that when any item and the relation to it are present to mind, the mind can generate in itself another item so related. "Noegenesis," a new termed coined by Professor Spearman from the Greek "nous" and "genesis," represents, he believes, a revolutionary doctrine of psychology—namely, that the processes described in the principles just enunciated possess the joint virtues of producing new mental content and of enabling the individual to attain belief on adequate grounds.

But though unassailable on the grounds of simplicity, Professor Spearman's laws, when it comes to their practical application—and to this over three-quarters of the book is devoted—fail to realize the hopes that their very clarity, hard intellectual quality, and comprehensiveness cannot but arouse in the mind of the reader. One feels throughout that a few questions, perhaps the most important, still remain unanswered. What, in essence, is this drive to create that differentiates the artist from his fellows? Why, having it, does he work in this medium and not in that, make this work of art and not another, select these images and not those? How does the aesthetic emotion of the artist compare with or differ from the aesthetic emotion of ordinary men and women who come under the influence of his creations? How far, indeed, do Professor Spearman's principles enable us the better to understand the mysticism of Dostoievsky or Blake, the ordered genius of Bach, or the intuition of Einstein? To suggest that these things are ultimately inexplicable is mere obscurantism; but even if the reader does not get from Professor Spearman's book, or from the admirably reproduced pictures that illustrate it, the sense that at last an adequate explanation has been offered, he will get, beyond the immediate pleasure of reading a work itself so exquisitely written as to merit inclusion among the products of creative mind, a habit of subjecting to intellectual analysis that part of artistic creation which even now is susceptible to such analysis, and guidance towards a new and very enjoyable way of looking at works of art.

GUY'S HOSPITAL REPORTS.

The last quarterly instalment of the eightieth volume of the *Guy's Hospital Reports*[3] opens with Sir William Hale-White's interesting article on the satirical prints of Thomas Guy, thus filling a gap left in previous accounts of the founder of the hospital. These represent him as a miser and usurer, and maliciously give an undeserved impression; for apart from his endowment of the Borough hospital Guy made a number of generous donations in other directions during his lifetime. The other sixteen articles cover a wide ground. Drs. Knott, Oriel, and Witts, reporting on the work of the asthma clinic since its foundation in 1928, state that among more than 200 cases dermal reactions to powdered allergens were positive in 46 per cent., eosinophilic sputum was found in 64 per cent., and Gram-negative bacilli of the Friedländer type in the sputum in 35 per cent. There is an increase of amino-acids in the blood during the attacks, and the urine contains a proteose to which the individual is specifically sensitive. The biochemical changes in the urine and blood are the result, not the cause, of the allergic paroxysm. Glucose exerts a beneficial influence in asthmatic children, but not in adults. Mr. Gill-Carey shows that abnormal conditions of the accessory nasal sinuses were present in twenty-four out of fifty asthmatic persons. Professor G. W. Nicholson continues his work on tumour formation in a philosophical study of the teratomas. The symposium on staphylococcal infections in the April number is now supplemented by Mr. C. H. Fagge's essay on osteomyelitis. In his stimulating article on abdominal orthopaedics, Mr. W. H. Ogilvie pleads for physiology as a basis for surgical treatment, and points out that the principles now underlying orthopaedic practice might with advantage be applied to all branches of surgery. Dr. Hurst singly, or in collaboration, contributes four short but interesting papers; in reporting a case of Addisonian anaemia in which treatment of gastritis was followed by restoration of gastric secretion, he points out that in cases without a family history of that disease and with evidence of gastritis, an

[2] *Creative Mind*. By C. Spearman, Ph.D., Hon. LL.D., F.R.S. Contemporary Library of Psychology. London: Nisbet and Co., Ltd., and the Cambridge University Press. 1930. (Pp. xii + 153; 6 figures, 16 plates. 5s. net.)

[3] *Guy's Hospital Reports*, vol. 80 (vol. 10, Fourth Series), No. 4, October, 1930. Edited by Arthur F. Hurst, M.D. London: The Lancet Ltd. (Annual subscription £2 2s.; single numbers 12s. 6d. each.)

attempt to cure the stomach disorder should be made, and may result in a cure without the continued use of liver preparations to prevent relapse. With one of his house-physicians he records a case of Addisonian anaemia with achlorhydria after gastro-jejunostomy performed for duodenal ulcer. With Professor M. J. Stewart of Leeds he describes a case of gastric carcinoma with miliary tubercles; the achlorhydria was not regarded as facilitating this infection. Dr. L. J. Witts writes on chlorosis in the male; Mr. W. M. Mollison on the treatment of vertigo by destruction of the labyrinth with alcohol; Mr. J. Gaymer Jones on duodenal ileus; Mr. R. A. Ratcliff on submucous lipoma of the colon. Dr. R. E. Smith places on record two rare conditions in infants, and the treatment of a case of haematemesis by gastric lavage is detailed by Dr. A. Nelson Jones.

PHYSICAL DIAGNOSIS

In 1905 Dr. RICHARD C. CABOT, now professor of clinical medicine in Harvard University, brought out his book on *Physical Diagnosis*. The tenth edition[4] has been revised so as to keep pace with the times, and is about the same size as the ninth edition, noticed at the time in our pages (1928, i, 310). It is dedicated to the late F. C. Shattock, a former Jackson professor of clinical medicine in Harvard University, in appreciation of his example of sincerity, common sense, and enthusiasm in the teaching and practice of medicine. The sustained popularity of this useful and well-illustrated volume is the result of the similar characters shown by the author, who in order to break down the unfortunate distinction between clinical and laboratory diagnoses has wisely described all the methods applicable to the examination of each of the several organs of the body (for instance, the stomach), in a single section, so that the student may pass directly from one to the other. The first chapter, entitled "Data relating to the body as a whole," deals briefly with variations in weight and in temperature, and then the various regions of the body follow, beginning with the head, face, and neck, the thorax being naturally considered in much detail and generously illustrated by skiagrams. The author's clinical experience is appositely utilized. Thus, to take one example, the normal intensity of the second sounds at the base of the heart varies at different periods of life; the records of 1,000 cases from his clinic showed that in 90 per cent. of children under 10 years of age the pulmonary second sound was louder than the aortic; in subsequent decades the number fell progressively until after the sixtieth year the aortic second sound was louder in 66 out of 68 cases examined; these figures are well demonstrated by two graphs. The concluding section is devoted to examination of the nervous system, and here as elsewhere the author limits his directions to the methods which he has himself employed and found useful, and does not attempt to give an impartial and impersonal account of all the investigations that have been recommended.

BIOMETRIC TECHNIQUE

The volume entitled *The Measurement of Man*[5] is the expansion of four lectures delivered in the University of Minnesota by research workers, dealing with different aspects of anthropology, but all versed in modern biometric technique. The late Professor J. ARTHUR HARRIS has discussed not only the familiar bodily dimensions, stature, weight, etc., but has also included a careful discussion of his own reductions of measures of metabolism. Professor CLARENCE M. JACKSON provides a study of the anthropometry of various racial stocks represented in the United States. Professor DONALD G. PATERSON, in an admirably written critique of the pseudo-scientific schools of character forecasters, from Lavater and Gall to our own time, well illustrates the power of modern statistical analysis. Lastly, Professor RICHARD E. SCAMMON summarizes what is known about the rate of growth not only of the whole body, but of its separate components. The essays are clearly written; technical terms and methods are properly explained, and the book can be recommended to any intelligent reader. All the essays are good, but that of Professor Paterson is of special interest to the medical reader.

THE OEDEMA OF BRIGHT'S DISEASE

Correction

In the review of Professor Achard's interesting book on *The Oedema of Bright's Disease*, published in our issue of October 11th, 1930 (p. 602), an unfortunate misstatement of fact was made, to which our attention has since been drawn. Our reviewer commented upon the apparent absence of mention of Southey's tubes as a means of withdrawal of fluid from the lower limbs. Actually, on page 226, which contains the last paragraph of the book, Southey's tubes are fully described and their value is indicated. We regret the mistake, and hasten to offer our apologies.

NOTES ON BOOKS

The November instalment of the *Annals of Medical History*[6] bears on its cover the portrait of John Syng Dorsey (1783–1818), a most brilliant member of the medical profession, who was prematurely cut off at the early age of 35 directly after his introductory lecture as professor of anatomy in the University of Pennsylvania. In his dissertation for the degree of M.D. he decried surgery as "the proof of the imperfection of medicine." He was the pupil and assistant of his maternal uncle Philip Syng Physick, the eminent surgeon, whose portrait forms the frontispiece. Dr. Walter Freeman sketches the life of Lewis Morgan of New Jersey, who in 1771, when 15 years of age, went to Edinburgh to attend the lectures of Cullen and Monro. The history of epilepsy given by Dr. T. C. Von Storch presents much interesting information. The late Dr. C. F. Hoover's article on "The significance of the scientific conquest of the air for intellectual freedom" does not, as perhaps might be anticipated, refer to flying, but to the struggle between science and superstition, and contains the aphorism that "Christian science is nothing more than modernized witchcraft." Dr. Ernest Caulfield concludes his valuable history of the infant welfare movement in London during the eighteenth century, and Professor A. S. Warthin's third part of "The physician in the dance of death," which it is to be hoped will later be published as a whole, deals with Holbein's share in the illustrations of this subject.

The fifth edition of Mr. WILLIAM PARTRIDGE'S *Aids to Bacteriology*,[7] which has appeared eight years after the last, has been revised and brought up to date by the inclusion of an account of several more human, veterinary, and plant diseases, as well as new sections on tuberculin tests, control of mosquitos, the chilling and storage of fruit, timber mycology, and bacteriophagy.

[6] *Annals of Medical History*. New Series, vol. ii, No. 6, November, 1930. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber Inc.; London: Baillière, Tindall and Cox. 1930. (Subscription in Great Britain, £2 5s. per volume of six numbers.)

[7] *Aids to Bacteriology*. By William Partridge, F.I.C. Fifth edition. Student's Aids Series. London: Baillière, Tindall and Cox. 1930. (Pp. vii + 311. 5s. net.)

The problems associated with multiple births have provoked both scientific discussion and also ill-founded speculations and beliefs. In a small volume, entitled *Twins: Heredity and Environment*,[8] Mr. HIRSCH presents the data obtained by an investigation of 108 cases of twins, his object being to determine the relative importance of hereditary constitution and environment in deciding the degree of similarity between such individuals. The first part of the book is devoted to a review of the scientific facts and opinions relating to the origin of twins. The second deals with the series of cases examined by the author himself, a new approach being made to the subject, in that the cases were selected not by random sampling, but according to a scheme whereby the similarities of identical and fraternal twins could be compared in similar and quite different environments. In this way the extent to which heredity and environment respectively contribute to the expression of mental and physical characters could be evaluated, and the analysis of these cases is of considerable interest in demonstrating that while both factors are concerned, heredity is the more important of the two.

The Mechanism of the Heart and its Anomalies,[9] by Dr. GÉRAUDEL of the University of Paris, is a translation of the French volume published two years ago. The author's interpretation of the anomalies of rhythm, based on anatomical and electrocardiographic studies, was briefly described in our issue of August 25th, 1928 (p. 344).

Mr. TOWNROE's survey of *The Slum Problem*[10] has been reissued, with a chapter on the Housing Act of 1930. The volume, as already noted in these columns, is an admirable study of insanitary areas dealing practically with the various problems and schemes of reclamation in Great Britain and America.

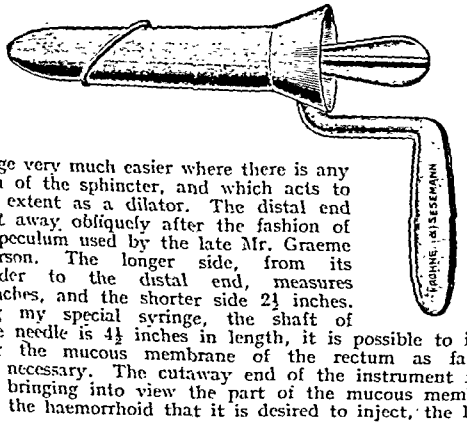
PREPARATIONS AND APPLIANCES

RECTAL SPECULUM AND LAMP

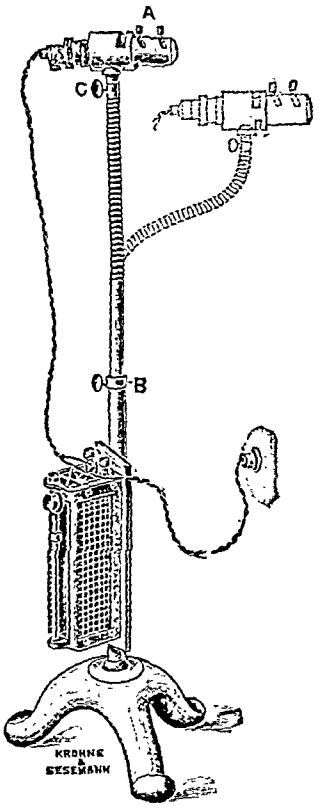
Mr. ARTHUR S. MORLEY, F.R.C.S., writes: The two instruments described below have been made in accordance with my design by Messrs. Krohne and Sesemann of Duke Street, Manchester Square, W.1. I have found each of them of material assistance in the treatment of haemorrhoids by submucous injections with carbolic oil.

The *rectal speculum* combines in one instrument several good features utilized separately in other patterns. The obturator is made with a conical end, which renders its



passage very much easier where there is any spasm of the sphincter, and which acts to some extent as a dilator. The distal end is cut away obliquely after the fashion of the speculum used by the late Mr. Graeme Anderson. The longer side, from its shoulder to the distal end, measures 3½ inches, and the shorter side 2½ inches. Using my special syringe, the shaft of whose needle is 4½ inches in length, it is possible to inject under the mucous membrane of the rectum as far up as is necessary. The cutaway end of the instrument facilitates bringing into view the part of the mucous membrane or of the haemorrhoid that it is desired to inject, the longer side keeping other parts out of the way like a retractor. A special point is the shape of the handle. This makes it possible to rotate the instrument *in situ* round a complete circle, because it is so designed that the horizontal part of the handle stands out clear of the buttocks and does not catch on them as does the ordinary straight handle. This is a much simpler arrangement than the movable collar, suggested by the late Dr. Whitcombe with a similar object.

The *standard lamp* affords a powerful light for illuminating the interior of the rectum through any form of speculum. Formerly I used a forehead lamp, but there are obvious disadvantages in being tethered by the cable of such an instrument. The lamp illustrated is arranged on a stand with a heavy base. The upright carries a rheostat, which makes it possible to use the lamp from mains of any voltage. The upper half of the upright is flexible, so that it can be



moved in all directions and to any angle. The lamp may be raised and lowered still further by pulling out the flexible portion from the rigid lower part after loosening the thumbscrew (B). The lamp itself is fixed on to the top of the column by a hinged collar (C), so that it can be tilted again at this point through an angle of nearly 180 degrees. The lamp is of the Vesta pattern. It is provided with two powerful movable lenses (A), by means of which the focus can be altered at will. It provides an intense circle of light, the diameter of which can be varied by moving it nearer to or farther from the field of operation. I have found it of the greatest assistance for rectal work. It can also be used for laryngoscopic or ophthalmoscopic work, and for microscopy.

EQUIPMENT FOR ACTINOTHERAPY

We have received from the British Hanovia Quartz Lamp Company, Limited, of Slough, a copy of their new catalogue containing particulars of equipment for artificial light treatment. This firm specializes in quartz *mercury vapour lamps* for general and local irradiation. First place is given to the Alpine sun lamp, which requires no accessory apparatus, and combines in its burner, its electrical controls, and its supports and directing and reflecting mechanism every device and adjustment which can make for ease and efficiency in operation. There is also listed a combination unit embodying an Alpine sun lamp for general irradiation and a Kromayer lamp for local conditions. Several variations and simplifications of the apparatus are shown in the catalogue. Another form of quartz lamp is after the design of Jesionek, for group irradiation in clinics.

British Medical Journal

SATURDAY, JANUARY 17th, 1931

VACCINATION AND ENCEPHALITIS

As announced in our last issue (p. 64), the Committee on Vaccination, appointed in 1926, under the chairmanship of Sir Humphry Rolleston, by the Minister of Health and the Medical Research Council, has now issued a further report. In passing, we may express regret that a committee concerned with "observations on the epidemiology and the clinical and pathological character of post-vaccinal nervous disease" should include no neurologist. The report begins with an analysis of ninety new cases of post-vaccinal encephalitis which have been reported in England and Wales during the two years ending September 30th, 1929. These cases do not appear to have brought to light any new facts concerning the incidence and manifestations of the disease. The chief incidence has again fallen upon children of school age, of whom at least 92 per cent. had not previously been vaccinated. Outbreaks have been correlated with an increase in the number of persons vaccinated, but not with the prevalence of other acute infective diseases of the nervous system. A familial incidence has been observed in four instances. The incubation period after vaccination has not differed from that previously observed. No single source of lymph has been impugned. An account of the clinical features and post-mortem findings in twenty-five fatal cases adds nothing to existing knowledge.

Drs. Fairbrother and Hurst, at the Lister Institute, have inoculated monkeys and rabbits with material from the nervous systems of seven patients who died, but without result; and they have failed not only to produce in animals any condition resembling post-vaccinal encephalitis, but also to demonstrate the vaccinia virus in affected brains. Four fatal cases of encephalitis following other acute infectious diseases—namely, variola, measles, and "influenza"—are reported, and the pathological findings in the nervous system in these cases are stated to resemble closely those of post-vaccinal encephalitis. Consideration is next given to the treatment of post-vaccinal encephalitis with the serum of individuals recently vaccinated. Sir Thomas Horder has treated a child with an intrathecal injection of the blood serum of its mother, who had recently been vaccinated. Hekman has employed intravenous or intramuscular injections of the parents' serum in eleven cases, and Grüneberg in two. Only two of the fourteen patients thus treated died, the others making a complete recovery. These numbers are small, but the committee considers the results suggestive enough to encourage the use of human antivaccinal serum at the earliest possible moment. Professor Ledingham and Dr. G. F. Petrie have prepared an antivaccinal horse serum, which is now available when human serum cannot be obtained. In view of the desirability of inoculating the minimal amount of virus necessary to secure immunity, experiments have been carried out with diluted lymph, and the results of these are described in an appendix to the report. It was found possible to obtain successful vaccination in 100 per cent. of cases with Government lymph in a dilution of 1 in 100, and such diluted lymph led to less severe local and general reactions than more concentrated lymphs. A further appendix consists of a translation of an extract from the report of the Smallpox and Vaccination Commission of the Office International d'Hygiène Publique, Part II of which is a valuable review by Sir George Buchanan of the more recent data obtained in regard to post-vaccinal encephalitis from different countries.

It must be confessed that we are still far from understanding the nature of post-vaccinal nervous disease and from explaining its peculiarities of distribution and incidence. Two alternative explanations present themselves: that it is directly due to the virus of vaccinia, and that it is produced by some other virus which (in the words of a contributor to the report) may be "directed against the nervous system by certain febrile or exanthematous diseases." Those who advocate the former view point to the remarkably constant chronological relationship of the encephalitis to vaccination, to the fact that encephalitis can be produced experimentally by vaccinia virus, which has been demonstrated in the brain in human cases by Blaxall, and to the beneficial therapeutic results claimed for the serum of recently vaccinated persons. The other school lay stress upon the pathological evidence. Histologically, they claim, human post-vaccinal encephalitis is quite unlike experimentally produced vaccinal encephalitis in animals, while it closely resembles encephalitis following measles, antirabies inoculation, and a febrile illness described as "influenza." Neither side can claim much help from experimental infection of animals, since neither vaccinal nor any other form of encephalitis has been produced in animals inoculated from the nervous systems of fatal cases. The crux of the question is, perhaps, How much stress can be laid upon pathological resemblances? As Dr. Russell Brain points out in his lecture on "Zoster, varicella, and encephalitis," which we publish in this issue, there are important clinical differences between post-vaccinal encephalitis, measles encephalitis, and varicellar encephalitis. To conclude that similar pathological pictures imply the same organism is to make what many will consider the rash assumption that the body cannot react in the same way to more than one infection.

If immune serum is proved to be effective in the treatment of post-vaccinal encephalitis, it will afford strong support to the theory of its vaccinal nature. For it appears extremely doubtful whether a secondarily invading organism which has produced an encephalitis could have its course "suddenly arrested," as the report suggests, by an improvement in the primary condition. If we consider the whole range of diseases, including disseminated sclerosis, characterized by perivascular demyelination in the nervous system, and recall their

many common characteristics, among others the fact that it is doubtful whether any of them have ever been transmitted to animals, we may justly wonder whether we are not here dealing with phenomena which are beyond the scope of our present neuro-pathological concepts, and involve more complex events than the simple invasion of the nervous system by an infecting organism.

THE DIABETIC CHILD

Insulin came into use in the latter half of 1922, and it is now possible to take stock of the present position of the diabetic child. It may fairly be said that no more severe test of the value of insulin treatment can be devised than that afforded by its use in a series of juvenile diabetics. In them, as is well known, the disease is almost invariably of a most serious type. In the old days the diabetic child died, and as a rule died rapidly; in the era of the Allen treatment it lived longer but precariously. Additional factors testing the success of insulin treatment in childhood easily occur to the mind: the necessity for growth and education, the frequency of epidemic infections and minor operations, and some would add, perhaps, the unreliability of the patient in the matter of obeying strict rules. The majority of practitioners must remember well enough the tragic circumstances of the child diabetic in the pre-insulin days, so that they have a clear picture with which to compare the results of modern treatment. What promise to these children does insulin hold out of survival, health, development, and capacity to take their proper positions socially in the world?

Given ideal supervision, survival seems assured. In 1928 E. P. Joslin and P. White[1] were able to report that in a special clinic of over three hundred juvenile diabetics the loss through death was only at the rate of one child per annum. Such a mortality is so low that it is justifiable to conclude that, as a class, juvenile diabetics are going to survive, and it is wonderful to think that hundreds of such children, constituting, so to speak, a new race of people, will be able, for the first time in history, to take their places in the affairs of the world. These survivors at present consist of two groups: diabetic children already ill at the time of the discovery of insulin, and those who have had the benefit of insulin treatment since the first symptoms of their disease. Comparison of these groups with cases of the pre-insulin days seems to show that insulin brings not only survival but health. It is too early to be assured that the late complications of diabetes can be altogether averted in those who have had insulin treatment from the start of their malady, yet the evidence on this point is most encouraging. P. White[2] in a recent paper (October, 1930) states that, in this group of cases, xanthoma, cataract, and calcification of the blood vessels of the legs are practically no longer seen as complications of the strictly treated diabetic child. On the other hand, she reports that three children whose diabetes started after August, 1922, have developed tuberculosis. As she found that in pre-insulin days such complications usually required something like seven years of disease to become at all frequent, it is only now that an opinion on this matter is beginning to be possible, and we must at present reserve judgement on what condition of health will be maintained by these surviving children. During the exanthems to which children are prone the dose of insulin requires to be adjusted to a higher level for the time being. As regards operations, Joslin mentions that of his cases one out of five had had some sort of operation without disaster.

Of special medical interest is the point whether with treatment by insulin from the very start of the disease any improvement in pancreatic function would be found. It might be thought that, if anywhere, such improvement would be noted in the diabetes of childhood. In practice, however, there seems no real evidence of such basic improvement. Growth, development, and education of juvenile diabetics present special problems. It has been shown by several authorities that the disease appears to choose the precocious type of child, one who is above the average in weight, height, and intelligence. S. F. Adams,[3] for instance, found that 30 per cent. of diabetics under the age of 20 years were more than 10 per cent. overweight before the disease declared itself. On these grounds the question has been raised whether the pituitary has an influence in starting diabetes in children. I. M. Rabinowitch and E. V. Bazin[4] have found that, although with the onset of diabetes growth and development slow down, they proceed quite satisfactorily under treatment.

The education of these children is somewhat difficult. At present it is impossible to think that they could go to boarding schools, either private or public; but the universities are within their reach, and already some are arriving at university age. Joslin mentions one diabetic being successful in both work and athletics at an American university, and further news of the late histories of those reaching adult life will be awaited with keen interest. The claim has been made that insulin offers "limitless hope" for the future of the diabetic child, and there are certainly grounds for anticipating that this claim will be substantiated.

SCIENCE AND ITS INSTRUMENTS

The mutual dependence of the instrument-maker and the scientific worker was again illustrated at the twenty-first annual exhibition of the Physical and Optical Societies, held at the Imperial College of Science, South Kensington, in the early days of this month. As Sir Arthur Eddington, who opened the exhibition, remarked, the instrument-maker generally does not profess to be scientific; he calculates out his curves and dimensions by trial and error. But it was interesting to hear the Plumian professor of astronomy at Cambridge go on to declare that that method might be as scientific as any other. Every year this exhibition

marks fresh progress towards the perfection of instruments. Apart from the increasing expense of scientific research of all kinds, it is a matter for regret also that, as appliances become more elaborate and exact, the amateur research and the ingenious improvisation which have evoked so much enthusiasm in past years have to be ruled out. The days of "tin tacks and sealing wax" are gone for ever, and a team of trained men, using material precisely adapted for the purpose, seems to be required in the provision of apparatus for any scientific adventure, whether it be the wresting of their secrets from the electrons or from the stars. To judge from the exhibition, progress in optics has now slowed down to a pedestrian pace, unless television be regarded as a branch of optics; and for the demonstrations of projected television there was actually an all-day queue at the Imperial College. But it is the study of acoustics that is now going forward, thanks to the stimulus of broadcasting, mechanized music in various forms, and the "talking" film. The elaborate devices for transmitting sound in public halls no doubt minister to the comfort of audiences, but the frequent complaint of inaudibility when these things are not installed—or sometimes when they are—makes one wonder whether this generation is growing deaf, whether a noisy age has not lessened the general sensitiveness of the civilized human ear. Audiences in former times, before these electrical or mechanical devices became possible, used to meet in the same halls, or in halls of similar dimensions, and there was no general complaint that speakers could not be heard. There is, of course, another possibility—namely, that the standard of enunciation and delivery has deteriorated. Science might consider giving us, not only ears to hear, but voices to speak. Of exhibits of another order, one which specially deserves mention was that of the Research Institute of the Cancer Hospital. This comprised various electroscopes for the detection of radiation and the measurement of the content of radium needles, also ionization chambers, a mechanical counter for the recording of blood cells of different types, and the fluorescent spectra of a number of compounds known to be productive of cancer in mice, the spectra appearing to act as a rough guide to their activity.

PATHOLOGY OF CARDIO-VASCULAR SYPHILIS

In a recent issue of the *American Heart Journal* H. S. Martland recalls the conflicting results of the earlier work, notably of Warthin and Clawson and Bell, on syphilitic involvement of the myocardium. He has investigated the modern view that such myocardial lesions commonly cause sudden death, by analysing 300 necropsies on patients who had died suddenly from heart disease. Cardio-vascular syphilis was present in 101, as compared with 139 deaths from arterio-sclerotic and 60 deaths from rheumatic heart disease. The lesions predominantly found in the specific group were aortic regurgitation (36), stenosis and atresia of coronary orifices (15), aneurysms (38), the remaining 12 consisting of unusual lesions. Myocardial hypertrophy was commonly observed, and was most evident in the presence of aortic incompetence; slight myocardial scarring was not infrequent, but was such as might well be associated with coexisting coronary arterio-sclerosis. Definite specific lesions of the myocardium occurred unusually, and were even then of insignificant extent. Regarding the biological development of cardio-vascular syphilis, the author believes that the process in early aortic syphilis is a retrograde lymphatic extension from the reservoirs in the mediastinal lymph nodes into the perivascular spaces around the vasa vasorum of the aorta. In this way is produced a syphilitic supra-valvular sclerosis, the most important lesion in syphilis of the aorta. It is triangular, and situated generally above a line encircling the commissures of the aortic cusps, and often just above the orifice of the left coronary artery. Aortic atheroma may coexist and may mask the syphilitic lesions. Extension of the pathological process takes place towards the commissures, widening them characteristically and spreading also into the free edges of the aortic cusps. During this extension of the syphilitic process the mouths of the coronary orifices are apt to become narrowed or even obliterated. The concomitant weakening of the wall of the aorta may lead to aneurysm formation, and this is specially likely to occur if the aortic valve remains competent. The aortic lesion should be regarded as a sclerotic deformity secondary to gummatous infiltration. A study of the gross pathology of the heart in cardio-vascular syphilis has been made by J. G. Carr, who gives the results of his analysis of 119 necropsies. Left ventricular hypertrophy resembling that secondary to essential hypertension was the only gross characteristic myocardial change. It was found that the frequent coexistence of arterio-sclerosis rendered very difficult the true etiological assessment of myocardial degeneration, but the author considers that rather less than 10 per cent. of patients with aortic syphilis have syphilitic coronary disease; 20 per cent. of such patients have aortic insufficiency, and this reflux is most apt to occur in enlarged hearts. Cardiac enlargement is thought to be a significant index of the cardiac involvement in cardio-vascular syphilis, and may be present even in the absence of aortic incompetence or hypertension. Aneurysm was found principally in those patients with relatively minor cardiac damage. Concerning the microscopic pathology in syphilis of the heart, C. C. Maher has made exhaustive examinations of the aorta at different levels, the aortic valves, the coronary arteries, the auricles and ventricles, and the septa, in five patients who died from untreated syphilitic aortic regurgitation. In these patients an inflammatory reaction was found represented by lymphocytic and plasma cell infiltration about the coronary arteries and their branches, and beneath the visceral pericardium. Invasion by the same cells of the spaces between the muscle fibres and around the capillary vessels was the typical form of myocardial involvement.

EFFICIENCY OF LIGHT WELLS

The increase in the height and size of modern buildings renders the internal well of the building of the greatest importance to the lighting of the inner rooms. When the building is high only a small portion of the rooms facing the well on the lower floors can have any view of the sky itself unless the light well is unusually wide; the remainder of the light entering the rooms must therefore depend on light reflected from the walls of the well. It follows from this that it is of the greatest

importance, in planning for the use of daylight in buildings of this kind, to know the amount of light received at various depths in a well of any given dimensions, when the surface of the well has a given reflection factor. The problem does not lend itself readily to mathematical treatment. It was therefore decided to investigate it experimentally, using the method of small-scale models. This has been done by Messrs. Meacock and Lambert for the Illumination Research Committee.[1] Diagrams are given to indicate the variations of "daylight factor" with depth in the case of light wells of different reflection factors. The curves show that any increase in the length of the well beyond about six times the breadth has no noticeable effect on the lighting of points on the centre line of the long wall. It was found possible to express the results in a simple empirical formula which would represent them with sufficient accuracy for practical purposes; this formula is given in the paper. Experiments were also made on the effect of glazed or matt surface brick linings to the well. A glazed brick well is less bright than a matt-coated well at the top, but brighter at the bottom if both wells have corresponding dimensions and the same reflection factor. The differences are, however, quite small, except at very considerable depths. It is intended that the whole of the methods of determination of the daylight factor outlined in this report, which are based upon experiments with models, shall in due course be compared with measured results on a few full-size light wells and in the rooms lit by them.

FIGURES FOR MEASLES AND WHOOPING-COUGH

The monthly epidemiological report for November, 1930, issued by the Health Section of the League of Nations, contains a valuable survey of the incidence and fatality of measles and whooping-cough in different European countries during the last two years. It is pointed out at the beginning of the article that the statistics of measles must necessarily be incomplete and to some extent unreliable, because many cases do not come under medical observation, or are wrongly diagnosed, and because in some countries possessing an excellent medical organization and facilities for medical statistics, measles is not notifiable. A study of the morbidity of measles in Bulgaria, Denmark, Hungary, Italy, Norway, Poland, and Switzerland in 1925–29 shows very marked fluctuation in its incidence from year to year. In Denmark in particular, where the arrangements for the notification of cases are both stringent and well enforced, the morbidity ranged from 958.5 cases per 100,000 inhabitants in 1923 to 50.8 in 1929. Correspondingly low figures were met with in 1929 in several other countries, suggesting that the rising wave of morbidity which had previously affected several countries had subsided. In spite of the fluctuations in its morbidity, the fatality of measles still remains high, notably in certain countries such as England and Wales, Germany, and France, where measles is one of the most fatal infectious diseases of childhood. Both in France and in England and Wales 90 per cent. of the deaths from measles occur in the 0–4 year group, the bulk of the fatalities within the first year of life taking place in the period 9–12 months. By reason of the lower vitality of male infants the fatality of measles is greater among them than among female infants, as is illustrated by the fact that while 1.02 deaths from measles occurred per 1,000 live births of both sexes, there were 1.08 male deaths from measles per 1,000 male live births and 0.96 female deaths per 1,000 female live births. Apart from clinical considerations the high case-fatality of measles can be explained by several factors, which include lack of care, unsatisfactory housing conditions, especially overcrowding, and illegitimacy. In a recent study of the seasonal rhythm of infectious diseases, Madsen has shown that while the maximum incidence of measles is liable to vary, its minimum incidence occurs regularly in September, especially in Denmark, and to a slightly less extent in Bulgaria, Scotland, France, Hungary, and Switzerland. As with measles so with whooping-cough, caution must be exercised in interpreting the statistics. Owing to the uncertainty of diagnosis, and the absence of official figures, the statistics of fatality are of more value than those of morbidity. A table of the death rates from whooping-cough in Bulgaria, Denmark, Hungary, and Poland during the period 1923–29 is given, showing that the rates per 100,000 population ranged from a minimum of 1.6 in Poland in 1929 to a maximum of 16.1 in Denmark in 1926. In most countries for which statistics have been available in recent years the maximum fatality rate for whooping-cough occurs in the spring, especially in the months of March and April. It is noteworthy that though in most countries, including Great Britain, there is a decided excess mortality for male infants generally, more girls than boys die of whooping-cough. In contrast with other acute infectious diseases there is no seasonal relation between whooping-cough fatality and its maximum or minimum morbidity.

GLANCES AT PRESENT-DAY SURGERY

A good deal of mud has been flung lately at the panel practitioner and the Insurance Acts, but, whatever their deficiencies, these are much less obvious than those of the sixpenny dispensaries and medical aid associations which have been displaced by them. There is plenty of evidence of this, but we have at present in mind, as a sign of vitality and interest in professional progress, the last quarterly issue of the *West Riding Panel Record*, the number of which—28—indicates that the periodical has been in existence for seven years. Besides paragraphs of insurance news and a thoughtful note on tuberculosis by Dr. W. Steven of Featherstone, entitled, "A difficulty in a panel practitioner's life," the *Record* contains an important article by Mr. H. Collinson of Leeds on some aspects of present-day surgery. The problems of surgery change from decade to decade, if not from year to year, and what seemed settled into routine practice a few years ago becomes once more subject for debate. Mr. Collinson deals judiciously with questions of abdominal drainage. Halsted has recorded his opinion that the deeper parts of a wound are less liable to microbial growth than the superficial parts; similarly Mr. Collinson states his belief that the peritoneum is less liable to infection than the tissues of the abdominal wall, and, in cases where drainage is thought advisable, it is these tissues, and not the peritoneum, that should be drained, while the peritoneal

wound should be closed. Exploratory abdominal operations, without clear indications of serious mischief, he condemns, as such patients are often neurotic, and if nothing is found they are worse off than before. The battle between non-operative and operative treatment of gastric and intestinal ulcers is still raging. The advocates of each method can claim successes. The clinical difficulty appears to lie in the choice of cases suitable for each. As regards duodenal ulcer, Mr. Collinson advises trial of medical treatment for a year or eighteen months before proceeding to operation. What the operation should be is a difficult question. He confesses that after a very large experience of the operative treatment of duodenal ulcer he is becoming much more conservative in his employment of gastro-enterostomy. That prostatic enlargement and its consequences should be mistaken for carcinoma of the stomach seems at first thoughts unlikely, yet such cases have been known to occur. Mr. Collinson gives a striking instance, in which the patient luckily escaped laparotomy and was cured by cystotomy and prostatectomy. Indeed, the surgery of the urinary organs holds out prospects of great advancement. No man in the present conditions of constant experiment and advance can dogmatize on the value of different methods of radium treatment of cancer. Much more extensive trials, and lapse of time, are needed before methods can be standardized (if ever) or results appraised. Some deaths under anaesthesia are no doubt wrongly put down to the discredit of the anaesthetic. On the other hand, a number of post-operative deaths from pulmonary complications which are the result of anaesthesia are not attributed to that cause. Pulmonary embolism apart, Mr. Collinson has no doubt that the incidence of bronchitis and pneumonia can be reduced by careful pre-operative preparation and removal of oral sepsis, by a wise choice of anaesthetic and its skilful administration, and the taking of every means to ensure adequate aeration of the lungs after operation. We can approve, though space will not let us follow, Mr. Collinson's *obiter dicta* on all the subjects dealt with, but we conclude with a hearty endorsement of his preference for the nurse who has acquired "a knowledge of real nursing, which in my view consists in the art of making a patient comfortable, the recognition of disquieting symptoms, the proper handling of an injured limb, and so on," rather than one with a superficial knowledge of anatomy, physiology, medicine, and surgery lacking the above-named essentials.

MUSIC IN THE OPERATING THEATRE

IN a paper contributed to the November issue of the *American Journal of Obstetrics and Gynecology* Dr. J. A. McGlinn says that owing to the unpleasant reactions from drugs, and the fear of complete loss of consciousness when using spinal anaesthesia, he has for the last year been employing music to divert the patients' minds from the thought of operation, as has previously been done by Donald Guthrie of Sayre before and after ethylene anaesthesia. Several hospitals have also added the radio to their theatre equipment as an adjuvant to local anaesthesia in tonsil operations on children. The advantages of music in the operating room are summarized as follows: (1) it creates a better atmosphere for all patients coming to the theatre, where it prevents the usual noises, such as the jingle of instruments and basins, and hiss of escaping steam, from being heard; (2) it diverts the attention of patients during operations under local and spinal anaesthesia; (3) it relaxes the tension of the surgeon and theatre staff during operations; (4) it entertains the "operating suite force" during the arduous tasks of cleaning up and preparation after the day's work is finished. Dr. McGlinn adds that jazz and sentimental tunes should alike be avoided, and that soft, soothing, melodious music is the type most acceptable to all patients. The music is supplied by a special self-playing automatic record-changing instrument with a superior type of reproduction.

ADVISORY COMMITTEE ON NUTRITION

For the purpose of advising the Minister of Health on the practical application of modern advances in the knowledge of nutrition an Advisory Committee has been appointed comprising the following members: Professor Major Greenwood, F.R.C.P., F.R.S. (chairman); Professor E. P. Cathcart, M.D., F.R.S.; Sir Frederick Gowland Hopkins, F.R.C.P., President of the Royal Society; Miss Jessie Lindsay; Professor Edward Mellanby, M.D., F.R.C.P., F.R.S.; and Professor V. H. Mottram, M.A. The members will hold office until December 31st, 1933, and will be eligible for reappointment. The secretary to the committee is Mr. F. R. Hudson of the Ministry of Health.

The staff of Charing Cross Hospital and Medical School has invited Professor Sigmund Freud of Vienna to deliver the next biennial Huxley Lecture at the Medical School. The lectureship was founded in commemoration of Professor Thomas Henry Huxley, a former student of the school. Previous lecturers include Lord Lister, Professor Virchow of Berlin, Professor Pavlov of Petrograd, Professor Simon Flexner of the Rockefeller Institute, New York, and Sir Frederick Hopkins.

The following lectures will be given this year before the Royal College of Physicians of London: Milroy Lectures, by Surgeon Commander S. F. Dudley, February 26th and March 3rd; Goulstonian Lectures, by Dr. Macdonald Critchley, March 10th and 12th; Lumleian Lectures, by Sir William Willcox, March 19th, 24th, and 26th; Oliver-Sharpey Lectures, by Professor Samson Wright, May 5th and 7th; Croonian Lectures, by Professor M. J. Stewart, June 4th, 9th, and 11th; Harveian Oration, by Dr. Robert Hutchison, October 19th; Bradshaw Lecture, by Dr. J. S. Fairbairn, November 3rd.

The seventeenth annual conference of the National Association for the Prevention of Tuberculosis will be held at Margate on June 25th, 26th, and 27th. It has been decided to devote the proceedings to an all-round discussion, divided into sub-headings, on the protection of the child from tuberculosis. The conference is open to all persons interested in tuberculosis on payment of the fee of one guinea, either as delegates or as private members. Application should be made to the secretary, N.A.P.T., Tavistock House North, Tavistock Square, W.C.1.

POST-VACCINAL NERVOUS DISEASE

THE ROLLESTON COMMITTEE'S SECOND REPORT

Reference has been made in an annotation published last week (p. 64), and in a leading article in to-day's issue, to the second report[1] of the Committee on Vaccination which was appointed in February, 1926, by the Minister of Health and the Medical Research Council, with Sir Humphry Rolleston as chairman. This document gives details of 90 cases of post-vaccinal nervous disease, brought to notice in England and Wales during the two years ending September 30th, 1929, and thus supplements Part II of the committee's earlier report. Twenty-five fatal cases were authenticated, and in respect of these the clinical information is correlated with the post-mortem findings.

Analysis of Cases

The report begins with an analysis of the 90 cases of acute nervous disease which had occurred, during the period under review, "within four weeks" of vaccination. Time and place incidence, the lymph used, the period between date of vaccination and onset of the nervous symptoms, and the clinical diagnosis or, in fatal cases, certified cause of death, are set out in tabular form. The interval between vaccination and onset in the 83 primary cases reported was two to fifteen days, with an average of 10.2 days. Of the 25 fatal cases in which the diagnosis of post-vaccinal encephalitis was confirmed, 23 followed primary vaccination. The groups of cases occurring in the Bristol area and in the Norfolk village of Wereham are examined in detail.

In regard to sex and age incidence, 42 patients were males and 48 females; the youngest was aged 20 months, and the oldest 55 years; approximately two out of every three patients were children of school age. Forty-seven patients recovered completely after an illness of from three days' to seven weeks' duration. One (a female) had not completely recovered after six months. No clinical features not previously observed were met with. There were 42 deaths, 41 occurring within three weeks of the onset, and 28 within seven days. Of the 90 patients, 83 had not previously been vaccinated; 3 had; and in 4 the question could not be determined. In 66 cases the lymph was obtained from the Government Lymph Establishment. Familial incidence was noted in four instances. Next follows a detailed account of the clinical features, post-mortem findings, and certain experimental investigations in 25 fatal cases of encephalitis following vaccinia, and of 4 following other acute infectious diseases; also an account of a recovered case following variola and/or vaccinia. The body of the report ends with a commentary summarizing the present position in regard to post-vaccinal nervous disease, from which we quoted the opening and closing passages last week (p. 65). While the present report adds no fresh facts to our knowledge of the pathology of post-vaccinal nervous disease, "the claim of certain authors that the lesions of post-vaccinal encephalitis are similar to, if not identical with, those of the nervous affections observed after certain acute infections, notably the exanthems, has received further support."

Treatment with Convalescent Serum

In regard to the results of treatment with the serum of convalescents, the report says:

"The cases cited supply a powerful argument for the use of human antivaccinal serum as a treatment which should be instituted at the earliest possible moment. At the present time whether or not this remedy happens to be available in this country is a matter of chance, and the committee suggests that the example of Professor Paschen might well be followed by the authorities of large residential institutions, particularly those which require recent vaccination or revaccination as a condition of admission. In default of human serum a member of the committee (Professor Ledingham), with the help of Dr. G. F. Petrie, has prepared by immunization of a horse an antivaccinal serum, which is now available for trial. Vaccinia admittedly supplies the direct stimulus to these conditions, and it may well happen that antivaccinal serum administered at the onset of cerebral symptoms—that is, at the period when the local and general effects resulting from vaccination are at their maximum—may by virtue of its content in antiviral bodies lead to fall of temperature and improvement in well-being. By such action the course of the secondary disturbance may be suddenly arrested, as apparently happened in the majority of the Dutch cases. It is, however, impossible in the present state of knowledge to exclude entirely a non-specific action of the serum similar to that of protein shock, which may manifest itself by rapid fall of temperature, and at least temporary amelioration of symptoms. In any case, such is the prognosis of post-vaccinal encephalitis that the empirical use of antivaccinal serum as early as possible after the onset of symptoms pointing to cerebral disturbance is strongly urged."

Appendices to the Report

There are three appendices. The first is a diagram showing (*a*) number of charges of lymph issued for public vaccination; (*b*) number of cases of poliomyelitis, polio-encephalitis, and encephalitis lethargica; and (*c*) number of cases of small-pox in relation to the incidence of cases which developed post-vaccinal nervous disease during the two years under review. The second appendix gives an account of some observations of the course of primary vaccination produced with lymph in greater dilution than that ordinarily used. It appears that there is little difference in the reaction to vaccination by lymphs in a dilution of 1:5 or 1:10, and that while 100 per cent. insertion success has been obtained with 1:100 this cannot be relied on. The general reaction to 1:100 lymph is less severe. The third appendix consists of two parts, each being extracted from the report of the Small-pox and Vaccination Committee presented to the Office International d'Hygiène Publique in May, 1930. Part I is a philosophical paper on variola minor and variola major by Professor Ricardo Jorge, entitled "Note on various designations of small-pox and their epidemiological and prophylactic significance." Part II is a review of the recent data obtained in regard to post-vaccinal encephalitis from different countries.

Post-Vaccinal Encephalitis in Different Countries

As in the earlier years covered by the Rolleston Committee's first report, the countries principally affected by post-vaccinal encephalitis during 1928 and 1929 were the Netherlands and England. The impression formed by the rapporteur, Sir George Buchanan, is that the accounts of these more recent cases accord very closely with those of the earlier series, and confirm the view that this complication of vaccination, when it occurs, may be regarded as forming a characteristic clinical entity. It has no doubt a parallel in the encephalitis which may complicate acute infectious diseases, such as measles, variola, and varicella. The possibility that post-vaccinal encephalitis is only a manifestation of the more general condition *encephalitis post-infectionem* has been urged by several writers, and it is most desirable that fuller data on this crucial point should be obtained. One general lesson brought out by Sir George Buchanan's review is that post-vaccinal encephalitis, though constituting an important practical problem, is extremely rare, and that it should not be allowed in any way to diminish the confidence placed hitherto in vaccination as a preventive of variola.

Nova et Vetera

SIR JOHN RICHARDSON

SURGEON, PHYSICIAN, SAILOR, EXPLORER, NATURALIST, SCHOLAR *

BY

D. A. STEWART, B.A., M.D., LL.D.

MEDICAL SUPERINTENDENT, MANITOBA SANATORIUM, NINETTE

Surely here is a long, full life of many enthusiasms that would have been after Osler's own heart! A ship surgeon fighting Napoleon, and on American duty in 1814, a physician also, a searcher after the North-West Passage in three expeditions, a naturalist—first to write about the fauna and flora of the Arctic Circle—a hospital administrator and reformer, Richardson lived to know Carlyle, to interview Florence Nightingale, and to find a job abroad for a keen house-surgeon called Huxley. Brought up literally at the feet of Robert Burns, who spent Sunday evenings in his father's home and chose the boy's poetry, Richardson lived to share the hobbies of Archbishop Trench and Max Müller, and to work out a study of the vocabulary of the ploughman poet.

John Richardson, son of Gabriel Richardson, one-time chief magistrate of Dumfries, and Anne Mundell, his wife, was born in Dumfries on November 5th, 1787, the eldest of an old-fashioned family of twelve children. In the very proper custom of the day he learned to read at home, and afterwards, at the early age of 4, was sent to school. In those days, and in purposeful, strenuous Scotland, no time could be wasted in merely being a boy. At the age of 12 he began a three years' apprenticeship to his uncle, an eminent surgeon of Dumfries. On the death of this uncle he was sent to Edinburgh, when not yet 14, to begin the formal study of surgery, which included chemistry and Greek. Before his seventeenth birthday he and his family, with due Scotch caution, considered the pros and cons of a house-surgeonship at the Dumfries and Galloway Infirmary, and decided in favour. There he was an earnest student and a reliable intern. In his eighteenth year, with already six years' experience, he returned to formal study at the University. Thrust thus prematurely into surgical studies and experience, the boy fortunately had a liking for nature and outdoor life, and delighted in long rambles in the country. This hobby, which was to become almost a vocation, shaped his whole life.

In 1806 Napoleon was upsetting Europe, and the British Navy was diligently on the job. It became this mature young man of 19 to consider both his country's need and the duty of getting a job for himself. His examination for an assistant surgeonship in the Navy "lasted only fifteen minutes and was quite easy." After a visit home he set off for London by the Glasgow mail, travelled three days unrestingly and uncomfortably, but economically, and arrived in London, as would be expected, in low spirits. Here he met his old companion, Robert Burns, junior, "began to speak English and walk straight," dined daily for a shilling on a plate of roast beef and a pint of ale, passed the examination of the Royal College of Surgeons of London, and was appointed, not yet 20, assistant surgeon to *La Nymphe* frigate. His ship mounted forty-four guns, and sailed well; the officers were civil, the commander congenial, and the young Scot wrote home: "We shall mess cheaply and comfortably."

Off Portugal there were "cutting-out" episodes—ships, of course, not tumours—in which the young surgeon gave evidence of soldierly spirit as well as surgical skill. So in the line of promotion he became senior assistant surgeon in the flagship *Hibernia*, acting surgeon of the *Hercule*—seventy-four guns—and, later the same year, when not yet 21, full surgeon to the *Blossom*, sloop of war. In 1812, at the age of 24, came a leave of absence, mostly devoted to study in London, where with characteristic forethought he laid out twenty pounds in taking permanent tickets for surgical and anatomical lectures, so that at any future time he might attend free of expense.

In the bitter winter of 1812–13 the Grand Army of France perished amid the snows of Russia, and Napoleon came back to Paris almost alone. But if France was quiet for a time, America was up in arms. The *Cruiser*, with Surgeon Richardson, scoured the northern seas for American privateers, was disabled and paid off, and the young surgeon got some further use of his London fees. In the summer of 1814 he was appointed to the First Battalion of Royal Marines, then in America, and, not liking service on the Great Lakes, marched and sailed with half the battalion from Montreal—greatly admiring Canadian trees by the way—for service along the coast of Georgia.

Richardson had no heart in this American service; he thoroughly disliked the "predatory system of warfare, which serves to degrade the British character without materially injuring the enemy," thought the British attack upon Washington, especially the burning of the public library, "barbarous," much worse than the conduct of half-civilized Russians in France, and was thoroughly uncomfortable about the seizing of the property of the unresisting settlers. Even so far south he had to deal with frostbites; and chilblains were the order of the day. Fortunately for the force, the two nations, and the world, peace was soon concluded, and shortly afterwards came the great general peace following Waterloo.

With peace came half-pay, two years' further study to add to his surgeonship the much superior status of physician, then marriage, and an attempt at practice in Leith. His graduation thesis, making use of his American experience, was *De Febre Flava*.

From the monotony of the beginnings of practice he escaped by applying for the position of surgeon and naturalist to the first Arctic expedition of Lieutenant, afterwards Sir John, Franklin. The report on his knowledge of natural history being satisfactory, he was appointed, and was made second in command of the expedition as well. It was his avocation, not his vocation, that brought him this appointment with its opportunities. When Richardson met Franklin he wrote of him as "a steady, religious, and cheerful man, and altogether an honour to the profession." Franklin might have written much the same of Richardson, though we doubt if he was so cheerful. The work expected of Richardson as naturalist was to collect minerals, plants, and animals, and observe phenomena generally. He confessed that his knowledge about these things was very limited, but did all he could to extend it, and looked forward to "a rich harvest in a country never before visited by a naturalist."

The Hudson's Bay Company ship *Prince of Wales*, sailing to York Factory in 1819, was held back by ice and nearly destroyed. On board with the party were men, women, and children, bound for Lord Selkirk's Red River Colony. Even the women took turns at the pumps. The delay cost the explorers a year of time, for they were forced to winter no farther inland than Cumberland House, and to spend a second winter at Great Slave Lake, before the real adventure began. In nearly two years of preliminary travel, preparation, and weary waiting, when Richardson the leader, or the surgeon, chanced to be at leisure, Richardson the naturalist was always occupied.

* Abstract of a paper read before the Section of Medical Sociology and History of Medicine at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

At the opening of the season of 1821, the party of twenty-five—British naval officers, Canadian voyageurs, and Indians—set out, against the advice of the fur companies' experienced travellers, carrying not more than a day's provisions, and having none *en cache* for their return journey, descended the Coppermine, reaching its mouth in July, and explored 550 miles of coastline to the eastward, before they decided at Cape Turnagain that it was time to get back to winter quarters. Then everything went wrong, and the story of the return journey is one of the grimmest of all the Northland epics. It is worth reading to see what human beings can endure. The leaders knew nothing of this kind of travel or of voyageur or Indian psychology. Eleven men were lost. Cannibalism broke out among the Indians. The survivors crawled back, gaunt skeletons, kept barely alive by half-rotted deer skins and charred bones scraped from the snow at their old encampments, and the scanty, unsatisfying, and griping lichen, *tripe de roche*. Richardson almost lost his life swimming with a line across a swift, icy river, and it fell to him to execute deliberately a crazed Indian cannibal.

In 1824—the year of his appointment to Chatham—it was resolved to attack the North-West Passage at three points—on both flanks and at the centre—Parry again on the east, Beechey through Behring Strait, and Franklin down the Mackenzie River. Again Richardson joined him as second in command, surgeon, and naturalist.

This time all the conditions were different. The leaders considered it, by comparison with the former journey, a sort of picnic party. While wintering on the lower Mackenzie, a mail from home arrived. To Richardson the people in England "seemed to be going mad about railroads, tunnels, steam engines, mines, diving bells," and he supposed "the mania would extend to Scotland also if there was money enough there to play the fool with." In 1827 the party arrived back in London. Richardson, who was now 40, resumed his duties at Chatham, worked steadily also over the narrative and scientific data of the second expedition, and now considered himself well enough equipped to begin a work he had long had in mind, his *magnum opus—Fauna Boreali Americana* or *Natural History of the Arctic Regions*, the first volume of which was published early in 1829 and the last nine years later, in 1838.

Shortly after the second expedition he was appointed chief medical officer of the Melville Naval Hospital, and in 1838 to the Royal Hospital at Haslar, near Portsmouth. Richardson was one of the first in Britain to dare to take insane people out of the dark cells in which they had been huddled like felons, to strike off their fetters and strait-jackets, and to put them into ordinary wards as patients. With the Admiralty he finally won the day for the new treatment, not by proving that it was more humane, but that it was less costly. He was also able to persuade the Admiralty, when a ship arrived off Portsmouth smitten with a most malignant type of fever, to let him take the sick ashore for fresh air and hospital care rather than leave them to swelter between decks in the rank air aboard ship.

In 1840 came promotion to the post of inspector of hospitals for the Admiralty, and the beginning of the publication of a series of papers, reports, and observations on a variety of subjects. It was at this time that he was knighted by the youthful Queen Victoria.

Franklin and Richardson returned from the second expedition in 1827. Three years later, John and James Ross, uncle and nephew, knocked again at the doors barred by icebergs and sealed by frost and snow. When years passed and they had not returned, Richardson offered to repeat substantially the expedition of 1825, and search the coastline of the solid continent eastward from the mouth of the Mackenzie. This offer was accepted, and Dr. John Rae of the Hudson's Bay Company consented to go as second in command. Richardson was now 62, and not the traveller he had been. He had a definite heart attack. In the spring he considered it the better plan, as indeed it was, to give Dr. Rae the leadership and let him try the coast again, with a small party, while he returned to England.

As a traveller he was simply omnivorous. All that he met was of interest to him. Observations of men and the ways of men, of places and events, but chiefly of rocks and trees, birds and flowers, fill two interesting volumes, published after the relief expedition. His many interests were often mingled, as when he studied together botany and Indian pharmacology.

"The *Heuchera richardsonii* (a saxifrage), which abounds on the rocks of this river, is one of the native medicines, its astringent root being chewed and applied as a vulnerary to wounds and sores. . . . The leaves of the *Ledum palustre* are also chewed and applied to burns, which are said to heal *rapidly under their influence. The cake of chewed leaves is* left adhering to the sore until it falls off. . . . The *Artoca alba* grows abundantly here. It is called by the Canadians 'la racine d'ours' and by the Crees 'musqua mitsu' (bears' food); a decoction of its roots and of the tops of the spruce-fir is used as a drink in stomachic complaints. . . . The *Acorus calorrus* is another of the indigenous plants which enter into the native pharmacopoeia, and is used as a remedy in colic. About the size of a small pea of the root dried before the fire or in the sun is a dose for an adult, and the pain is said to be removed soon after it is masticated and swallowed. . . . A drop of the juice of the recent root is dropped into inflamed eyes, and the remedy is said to be an effectual though a painful one. . . . The *Geum strictum* grows plentifully on these portages, *and is used by the natives for the purpose of increasing* the growth of their hair. They dry the flowers in the sun, powder them, and mix them with bear's grease. . . . The dog bane and Indian hemp grow luxuriantly on the sandy banks of this river. They abound in a milky juice which, when applied to the skin, produces a troublesome eruption. . . . The second-named species grows more robustly and erectly than the other, and furnishes the natives living on the coast of the Pacific with hemp out of which they form strong and durable fishing nets."

The journal of the relief expedition had two hundred and forty pages of separate and detailed appendices on geography, geology, climatology, the sequence of events in the seasons at various places in the North, the thermometer, the distribution of plants north of the forty-ninth parallel, cereals in the North, a forty-page appendix on trees and shrubs, a twenty-page list of plants, and, to complete the whole, a list of insects.

Still expeditions went and came, adding much to our knowledge of the Arctic regions, but little to the story of Franklin and his fate. Four medical men, it may be observed, were leaders of expeditions: Sir John Richardson, Dr. John Rae, Dr. Elisha Kane—whose journal has almost as much to say of scurvy as of polar ice—and Dr. Hayes. It was Dr. John Rae who finally, in 1853, eight years after Franklin had set out, chanced upon traces, and indeed skeletons also, of the ill-fated party. In the meantime, searching expeditions had mapped 7,000 miles of new coastline. The saying that summed it all up best, and was carved on the London monument to Sir John Franklin, was Richardson's: "They forged the last link with their lives."

Among the young surgeons who served at Haslar under Richardson several rose to high places and one to fame. Thomas Huxley dedicated to his old chief his *Oceania Hydrozoa* and, what is better, left a pen picture of him in what must have been his later days. With Huxley at Haslar under Richardson were Andrew, afterwards Sir

Andrew, Clark, and two future directors-general of the medical service of the Navy, Sir Alexander Armstrong and Sir John Watt-Read.

After nearly half a century in the medical and surgical services of the Navy, Sir John, now 68, retired from formal duties. The ten years of evening which rounded out his life were as full as any of its earlier decades, occupied with interests that had been interrupted in the years of daily duties. He travelled and observed, dug up Roman remains, came to be an authority about these also, and kept up associations with a wide circle of men of kindred spirit. He fell whole-heartedly into the new interest in the study of words aroused by Max Müller and Archbishop Trench, and contributed to the dictionary of philology a complete index of the words used by Robert Burns, with their significations and cognates in Norse, Icelandic, and Gaelic. Living in the country, his professional skill was always at the service of his neighbours, great and small. After a life full and useful, and after a day pleasantly occupied, he drew a long breath, and was dead.

To follow the successive steps in Richardson's professional training and work is almost to live for an hour in the very medical world of the first half of the nineteenth century. And men of our Northland should have a special interest in one who traversed it in three laborious expeditions, lived nearly eight years in it, and a lifetime in working over its natural history. Plants of Northern Canada named by and for Richardson would make a garden of respectable size, and animals named by and for him a considerable zoo. Among the plants are, to use the common names, lady's slipper, black currant, desert willow, dwarf cinquefoil, mountain avens, buffalo plum, tick seed, blueberry, gentian, twine berry, bastard toadflax, sand daisy, prairie ragwort, pond weed, spear grass, bunch grass, wire rush, alum weed, loco weed, beard tongue, one of the asters and *Entocha franklinii*, which, it would seem, Richardson introduced into the gardens of England. Among the animals are the Franklin ground squirrel or scrub gopher, the Richardson ground squirrel or flicker tail, the Richardson kangaroo rat, Richardson's water shrew, and the Richardson northern skunk. Then there are the well-known Franklin gull and the Richardson owl. Let it be remembered to his credit by the more practical among us also that while almost to our own day the forty-ninth parallel was supposed to be about the northern limit for wheat-growing, Richardson, a half-century earlier, placed the limit about the sixty-fifth parallel, and reported upon cereals actually growing there and then.

He had in his life many of the conventional honours, and some special marks of distinction as well. His was perhaps a life of industry more than a life of genius, but it was a full, good life, and in many ways even a great life. It is not every day that we meet in one person—surgeon, physician, sailor, soldier, administrator, explorer, naturalist, author, and scholar, who has been eminent in some roles and commendable in all.

HEALTH OF THE SCHOOL CHILD

SIR GEORGE NEWMAN'S REPORT *

Education and Training of the Blind, Deaf, and Lame

In 1929 the number of school children ascertained to be blind or partially blind was 1,736 and 5,354 respectively, being a decrease of 151 in the first and an increase of 129 in the second category, compared with 1928. There are 4,647 school places for these children. It is estimated that at any one time there would always be some 200 children who, for reasons other than lack of accommodation, would not be in attendance at any special school. There is apparently no general shortage of accommodation for the totally blind in the country as a whole, but the provision for the partially blind is admittedly inadequate. Of the present blind population, the largest proportion become blind in the first year of life, though this proportion is progressively diminishing year by year. The next largest proportion become blind between the ages of 60 and 70 years, and this proportion is increasing annually. During the period from 1919 to 1929 there has been a gradual diminution in the proportion of persons becoming blind up to 40 years, and a gradual increase in the proportion becoming blind after that age. This rising proportion of the late blind has been inevitably accompanied by an increase in the number of unemployable blind—an increase which is probably more apparent than real owing to fuller investigation. The number of blind under training is increasing year by year, and the number trainable but untrained is decreasing.

School children ascertained to be totally deaf in 1929 numbered 3,769, compared with 3,935 in the previous year. Fifty schools for the deaf and partially deaf give a total accommodation for 4,696 children. Mr. P. M. Yearsley of London investigated the causes of deafness in 122 children seen during the year. In 5 of these the cause of deafness was doubtful, in 29 it was congenital, and in 91 it was acquired. Most of the congenital cases were those of sporadic deaf birth. Of the acquired cases, more than half were caused by primary ear disease, and a fourth by infectious fevers. Measles and scarlet fever head the list with 58 and 25 cases respectively.

New schemes for the treatment of orthopaedic cases were approved in seventeen areas, bringing the total areas making such provision up to 200. There are 228 out-patient clinics maintained by local authorities—an increase of 37. In approved schemes the provision made covers both in-patient treatment at hospitals or hospital schools and after-care treatment at local clinics. Earlier ascertainment is leading to earlier treatment, and consequent prevention of crippling defect. This encouraging result, which is being brought about mainly by popularizing the clinics and by obtaining the friendly co-operation of the local family doctor, is indicated by the demand for, and appropriation of, a larger number of hospital beds for infants and by the increasing attendance of infants at the orthopaedic clinics. The report mentions that not infrequently, when a mother brings her child to the family doctor for influenza or some other ailment, he discovers that the child is suffering from poliomyelitis in an early stage, or from some slight congenital defect. In these circumstances the child would probably be referred to the clinic.

Artificial Light Treatment

Light treatment is provided by 78 education authorities—14 more than in the preceding year. The former enthusiasm with which, in some quarters, ultra-violet therapy was hailed as a panacea for all ills has evidently given place to a more scientific, unbiased, and inquiring attitude. The experiences of many are summed up by Dr McLaren in the Lincolnshire report as follows:

"Cases of malnutrition due to some recent acute illness improve very quickly under the light treatment. On the other hand, I did not find any very great improvement in the condition of children suffering from chronic malnutrition."

Secondary School Children

With the notable exception of deformities, the incidence of various defects among secondary school children is either approximately equal to, or more usually lower than,

* Notice concluded from page 70.

that found among elementary school children. In malnutrition, skin diseases, squint, external eye diseases, and defective hearing it is considerably lower; while in defective vision, organic heart disease, and nervous disease the incidence is about the same. The apparent heavy incidence of deformity among secondary school children is explained by the recording of minor postural deformities.

A comparison of the returns for the past four years reveals that the general health and fitness of these children is improving. In no case has the incidence of a particular defect increased, and many have diminished. But a warning note is sounded. There is a large amount of "subnormality," not amounting to malnutrition, but which, related to the competitive strain of the secondary school curriculum, may lead to serious conditions of ill-health. The burden, in a large measure, is inevitable, but its existence should not be disregarded or overlooked, for it is of vital importance to healthy adolescence that the secondary school period should be used to safeguard and fortify both the physical and the mental constitution. "A healthy body and brain are of more value than an immediate intellectual achievement."

The Teaching of Hygiene in Schools

Since 1907 several circulars have been issued by the Board of Education directing attention to the importance of regular instruction in hygiene in schools and in training colleges. As late as 1927 a handbook of suggestions to teachers was issued, in which it was stated that "the *study* and *practice* of health must form, from the first, part of the everyday life of the school." The handbook of the following year advocated as one of the minimum requirements that hygiene should be systematically taught at least once a week, and practised every day throughout the nine years of the child's school life. In 1930 an inquiry was made into the present position of hygiene teaching in schools through the co-operation of the school medical officers. Sir George Newman concludes:

> "I am afraid that the experience gained, as a result of the inquiry, leaves some doubt on my mind as to whether school medical officers generally have fully appreciated their responsibility in this particular matter, or whether their other duties have taken undue precedence over the discharge of this duty. However that may be, it is obvious that school children should learn by practice and by direct instruction the healthful way of life, and that the school doctor has responsible duties in this behalf. The ultimate aim and purpose of the work of the school medical officer is not only the detection and treatment of disease and defect, but that by conference with, and advice given to, the authority, teachers, and parents, the school doctor may take his full part in advising on the conditions necessary to create and maintain all-round healthfulness. Among these are the condition of the school and the practical and class instruction given in matters of health."

In approximately one-third of the senior boys' schools no definite or systematic instruction was found to be given in the subject of hygiene, and no systematic provision seems to be made in 85 per cent. of the boys' secondary schools and in 45 per cent. of the secondary schools for girls.

The condition of things revealed by this inquiry is not new. The teaching of hygiene has always presented difficulties to the school teacher. There are several reasons for this. The first is that the school curriculum has not always included hygiene as an integral and necessary subject. Secondly, hygiene is sometimes not regarded as educationally important by those in immediate authority. Thirdly, it is not easily measured, tested, or inspected; nor is a knowledge of it acquired without some difficulty. The subject cannot be so readily "crammed" as some others, nor can it be easily graded or prescribed within narrow limits. Fourthly, its far-reaching comprehensiveness involves the home as well as the school, and its lessons inevitably raise all sorts of subsidiary issues. For example, to teach cleanliness in an unclean school to children coming from an unclean home seems impracticable and ineffectual; to teach health of the body seems to trespass upon the professional field of the doctor, in which the teacher does not feel at home; again, instruction and advice give rise to domestic and personal questions which may be misunderstood and become a source of grievance to the parents.

The ignorance of children in regard to healthy living and their failure to acquire and practise healthy habits is impairing much of our educational effort and producing in after-life a burden of disease, disharmony, and incapacity, which is extremely costly in both wastefulness and remedy.

It would seem that the first requisite is still a much fuller understanding of the place for, and the need of, school hygiene. In creating or securing this understanding the school doctor should be the best interpreter and leader. He is sometimes restricted to the role of recorder, and is not a pervading influence. In some areas there is a tendency to restrict his sphere, and his advice is uninvited, side-tracked, or disregarded.

The survey includes a detailed summary of the work of the school dental service, with estimates of the pressing need for its extension and development. In this connexion a summary is given of a detailed investigation by Mr. A. T. Pitts of London into the arrangements for dental inspection and treatment in ten representative areas. His report contains a strong recommendation to authorities employing a staff of school dentists that a supervising dental officer should be appointed whose chief duties would be organization and supervision.

Various matters are dealt with in a series of appendices—for example, the story of the school medical service, nursery schools, infective disease and mortality among school children, rheumatism in childhood, external eye diseases, provision of school meals, and special inquiries made by school medical officers during 1929. Each of these appendices would justify a separate review, and all of them will amply repay study.

THE MAUDSLEY HOSPITAL AND THE MENTAL TREATMENT ACT

The London County Council has been considering the extent to which, under the Mental Treatment Act, provision for voluntary and for temporary patients should be made in supplement of, or substitution for, the existing accommodation for patients coming in under reception orders. Its conclusion is that voluntary patients should be received at such of the London county mental hospitals as possess adequate admission villas or units. Some of these patients will already have had experience of the mental hospitals, and will realize the advantage to be gained from treatment there should they feel a recurrence threatening them. It is thought also to be a good thing to associate as far as possible with the work of the existing mental hospitals the hopeful treatment of voluntary patients. At the same time the Council realizes that it will be impossible to rely entirely and at once upon such accommodation for voluntary patients as may be set apart in the mental hospitals. The margin of accommodation available for patients requiring care under reception orders is so small that it is scarcely possible to keep abreast of the requirements, and there is no room for the further developments which will be necessary if voluntary patients are to be received in large numbers. The Council will also be expected to make

some provision of a more particular nature for the needs of such voluntary patients.

In these circumstances the London County Council has considered the special position of Maudsley Hospital, an institution specifically devoted to early cases of nervous and mental disorder, which is able to receive voluntary boarders and in practice has never received any patients other than voluntary ones. It is therefore proposed to reserve Maudsley Hospital for the reception and treatment of the voluntary patients provided for under the Mental Treatment Act, and it is particularly hoped that this hospital will continue to be entirely dissociated in the public mind from any connexion with compulsory detention. If and when persons received at Maudsley lose their volition, or if some form of detention becomes necessary without or against their will, they will have to be removed from that particular institution. In order to ensure a proper public appreciation of this hospital's special function and usefulness, it is proposed to appropriate the hospital, under Section 265 of the Lunacy Act, 1890, for the purpose solely of the reception of voluntary patients. That is, and always has been, its function, but by this technical method of appropriation it is hoped to establish it beyond doubt in the public mind. It is also proposed to ask the Board of Control to make special modified rules for application to an institution like Maudsley Hospital, provided by the local authority for the purposes of the Mental Treatment Act, in which only voluntary patients are received. It is recognized that a great part of the value of the Maudsley Hospital lies in the opportunity for clinical instruction which it affords, as a school of the University of London. In the past the position of the hospital has been unique, but the Mental Treatment Act will tend to unify administrative procedure in connexion with the treatment of voluntary patients at all institutions which will receive such patients, and the London one will no longer hold a singular position in this respect.

It is considered that the provision for temporary treatment, without certification, of persons incapable of expressing willingness or unwillingness to receive such treatment will not create for the Council the problem of making accommodation for a new type of patient in increasing numbers. The temporary patient, it is thought, will be found to be clinically identical with the kind of patient already received to a large extent in the county mental hospitals. Such patients can be received quite properly in the admission units of those mental hospitals which have developed accommodation of this type, and no distinction need be made between temporary patients and the new cases received under order, provided that both are put in an environment which makes due provision for classification and segregation of individuals who will be disturbing to others. It is proposed to develop specialized arrangements for temporary patients where these can best be provided, and in this connexion it is believed that the Ewell colony, which is designed entirely on the villa principle, will be specially suitable.

With regard to out-patients, attention is drawn to the comments contained in the Board of Control's memorandum. The Board contemplates association between the staffs of mental and of general hospitals in the establishment and administration of out-patient mental clinics. The Mental Hospitals Committee of the London County Council reports that in London especially such association will be needed, for the Council's mental hospitals, with the exception of the Maudsley, Fountain, and Tooting Bec institutions—the two latter being transferred institutions, and technically not mental hospitals, but workhouses—are all outside the London boundary. It is understood that detailed arrangements for after-care will be presented at a later stage.

Scotland

Milk and the School Child

For several years the Department of Health for Scotland has been actively engaged in the investigation of milk as an important factor in the diet of the school child. In 1927 and 1928 various researches were carried on, but as the results were obtained from only 1,200 children, a much bigger scheme was devised to include 20,000. During the first half of 1930 Dr. Gerald Leighton and Dr. Peter L. McKinlay, assisted by Dr. John Macintyre, chief medical officer to the Education Authority of Lanarkshire, and by teachers in the selected schools, conducted a series of experiments with various types of milk. The cost of the investigation was borne by grants of £5,000 from the Empire Marketing Board, and £2,000 from the Central Advisory Committee of the Distress and Mining Areas (Scotland) Fund, to which was added £477 4s. from private funds. Lanarkshire was chosen as the area most suitable for the test, as the schools were all situated in industrial and densely populated parts, where unemployment was rife, and thus domestic extras unobtainable; it was possible, therefore, to eliminate the criticism previously applied, that the improvement in the children might be due, in part, to better domestic conditions during the period of trial. The milk supply came from twenty-six herds situated in different parts of Scotland. Bulked Grade A (T.T.) milk was used, and the strictest medical supervision was kept throughout. A central receiving depot was established in Glasgow, this being visited several times a week by one of the investigators, who was responsible for the standardization of the daily ration. The issue of the milk to the schools was carried out under the strictest hygienic rules, all risks of infection being eliminated. Half the number of children were used as controls; it was therefore necessary to provide 10,000 with milk, each child receiving three-quarters of a pint daily. A further distinction was made, in that 5,000 of the children consumed raw milk, while the remainder took it in pasteurized form. The selection of the children was made with great care, the teachers being left to decide as to "feeders" and "controls"; and, fully realizing the importance of using an average type of child, they adopted either the method of ballot or that of alphabetical election; thus the children were neither weakly nor over-robust. Regular records of height and weight were kept. The report,[1] just issued, states that on the whole the parents were in sympathy with the test, and gave ready assistance. The teachers themselves were enthusiastic over the results, and, quite apart from the purely technical aspect of the test, they noted that the children, both in body and in mind, were much more buoyant and lively. The conclusions arrived at are that the addition of milk to the diet of children has a striking effect in improving physical and general health, and in increasing mental alertness. No obvious or constant differences occur between boys and girls, and the results are rarely influenced by age, the older children benefiting as much as the younger. There is no special advantage in pasteurizing milk, and the question of the relative merits of the two varieties must remain open. But it is certain that pasteurized and separated milk as a supplementary ration to the usual variable and mixed diet of the household is a potent growth-producing factor. The results agree with those recently obtained in London and elsewhere, and it is clear that, with new powers, local authorities may consider the recommendation of an additional ration of graded milk for all school children. This (as Dr. Parlane Kinloch says in his prefatory note)

[1] Department of Health for Scotland. Milk Consumption and the Growth of School Children. H.M. Stationery Office. 1930. (3d. net.)

would have far-reaching results in eliminating tuberculosis from the dairy herds, and generally improving the quality of the Scottish race.

Education of the Deaf

The Education Committee of Edinburgh Town Council has now considered objections lodged against the draft scheme of the Educational Endowments (Scotland) Commission, which was summarized in the *British Medical Journal* of November 15th, 1930 (p. 841). The scheme proposes to convert the building and the funds of Donaldson's Hospital into a Royal Edinburgh School for the Deaf. The main criticism was directed against the erection of boarding-houses for the children under training in the grounds of Donaldson's Hospital, and opposed any alteration of the architectural characters of this building, which is a distinctive feature of Edinburgh. The report containing the proposals as already outlined, and embodying the above recommendation, was approved.

Larbert Mental Hospital

The fourteenth annual report of the Stirling District Board of Control for the year ended May 15th, 1930, dealing with mental disease in the counties of Stirling, Dumbarton, West Lothian, and Clackmannan, has just been issued. This is the last annual report under the old system, the mental hospital at Larbert being now under the management of a joint committee consisting of twenty-ive representatives from four counties and four burghs. According to the report of Dr. R. B. Campbell, medical superintendent of the Stirling District Mental Hospital at Larbert, there were 964 certified patients on the hospital register at the beginning of the year, 548 being males and 416 females. The total number of patients under treatment during the year was 1,243, 279 certified patients being admitted. The average age for both sexes was 43. Only 49 of those admitted were in normal bodily health. In regard to causes of insanity there were 38 cases of senile insanity, 21 of general paralysis and insanity resulting from gross brain disease, 13 of epileptic insanity, 13 of congenital mental enfeeblement, and 3 of encephalitis lethargica. Alcoholic excess and serious bodily illnesses were assigned as causes in 13 and 26 cases respectively, while senility was responsible in 38, syphilis in 14, organic brain disease in 5, and epilepsy in 13. In 67 cases the mental breakdown had occurred at a critical period of life; 5 cases were ascribed to childbirth. At the beginning of the year there were 24 voluntary patients, and 16 others were admitted during the year. In that period 12 voluntary patients left the hospital cured. Service patients, maintained by the Ministry of Pensions, numbered 46, one being a voluntary patient. Of the 173 patients discharged during the year, 105 are stated to have been cured, giving a recovery rate on the number of admissions of 37.3 per cent. for both sexes. The report comments favourably on the system of allowing patients to go home on pass before final discharge. Such a patient might be sent back to the institution without any formality within a trial period of twenty-eight days. Out of 16 patients who were provisionally discharged under this system, only 2 had to return for further treatment. The number of deaths during the year was 83, the death rate calculated on the average number resident being 8.4. This is 1.3 lower than the average death rate since the opening of the hospital. In referring to treatment Dr. Campbell draws attention to the success which has been obtained in treating early cases of general paralysis with tryparsamide and malaria. He also mentions that over a hundred patients benefited from treatment in the electrotherapeutic department of the hospital, and that occupational therapy has been one of the most useful agents in promoting recovery and contentment. Outdoor employment is provided by a large garden and farm, where an attempt is being made to establish and maintain a tubercle-free herd of cattle. The report of the chairman of the District Board of Control states that the weekly cost of board per patient during the past year was 18s. 1d., which is rather less than the average rate for other mental hospitals in Scotland. It also points out that if a separate institution for mental defectives were established in the neighbourhood, about a hundred patients could be transferred from the Larbert Mental Hospital, which would relieve the present congestion, and postpone the necessity for further additions to the hospital buildings.

England and Wales

The Lister Institute

On December 18th, 1930, a large company of staff and other research workers, past and present, met in the library of the Lister Institute of Preventive Medicine to offer parting gifts to their two distinguished colleagues, Sir Charles Martin and Professor Arthur Harden, on the eve of their retirement. Professor Ledingham, who is succeeding to the post of director, presided, and referred to the fact that only a few years ago a very similar gathering had assembled to express the great satisfaction which the conferment of knighthood on their director had given them, and to celebrate the occasion by presenting him with his portrait. They were not accustomed at the Lister Institute to retirements of staff on account of age, and it was a matter for mutual congratulation that Sir Charles Martin and Professor Harden had reached the prescribed age-limit while still in their full mental vigour. Sir Charles had directed the activities of the Institute for twenty-seven years. His highly successful administration might justly be attributed, in the first instance, to the charm of his personality, and secondly to his tact, his business ability, and the catholicity of his scientific interests. Professor Harden had served the Institute for thirty-three years, and as biochemist-in-chief during that period had made his department an important centre of biochemical research. Only a year ago he had been awarded a Nobel prize in chemistry for his work on fermentation. The departure of Sir Charles Martin and Professor Harden would mean a severe loss to the Institute's forces, but it was to be hoped that the traditions they had set would long remain a potent source of inspiration to their successors. On behalf of the many subscribers at home and abroad Miss Harriette Chick was called upon to present to Sir Charles and Lady Martin a silver coffee service designed and executed by Mr. P. S. Alexander of Walberswick, Suffolk; and Miss Muriel Robertson unveiled and presented to Professor Harden his portrait in oils by Mr. Neville Lewis. Sir Charles Martin and Professor Harden, in returning thanks for these gifts, referred to the developments they had witnessed in the scope of the Institute's activities during their long service, and at the close of the reception, which concluded the ceremony, they took leave of their colleagues. Sir Charles and Lady Martin sailed on January 2nd for Capetown, *en route* for Australia.

The Cicely Northcote Trust

It is evident from the annual report of the Cicely Northcote Trust for the year ended October, 1930, that its beneficent work in relieving the distress of patients at St. Thomas's Hospital, London, continues to be carried out with undiminished enthusiasm. In 1910, when the first report was issued, the almoner's services were comparatively limited in scope, being confined to the casualty

and out-patient departments. Much of the pioneer work of the Trust has consisted in organizing and co-ordinating social services for the benefit of patients in the wards, and in securing for those in need of personal and individual care the most favourable conditions for early and permanent recovery. For one patient, whose difficulties are described in the present report, grants were obtained from three different organizations, and contributions by the patient herself were arranged to be made in convenient instalments. During the year 9,000 patients were visited in the wards, and convalescent provision was made for almost 900—occasionally for long periods. The work of the Trust, however, is not restricted to financial assistance, but touches nearly every aspect of social and domestic life. Among its manifold interests is the after-care of cancer patients, who are regularly visited and given advice and help in money or in kind. A complete record is kept of every cancer patient who passes through the wards of the hospital. Besides maintaining a hostel for rescue work, the Trust has organized a club for fathers and mothers, which was fully described in the previous report. This club now occupies more extensive premises in Royal Street, but £1,200 is still required to complete the cost of the building. It is a striking tribute to the efficient administration of the Trust that Miss Macintyre, its head worker, was invited to Australia to assist in founding an almoner's department in Melbourne Hospital.

Correspondence

THE SWEDISH MEDICAL CURRICULUM

SIR,—In the *British Medical Journal* for January 3rd Dr. Munro Kerr states that Sweden has "the longest curriculum of any country—namely, eight to nine years." This statement as to the length of the Swedish curriculum has been made several times recently in important publications. Presumably, the period of 8 to 9 years is thought to be comparable with our British period of 5 academic years. This is a misconception of the Swedish curriculum. The Swedes are a race of great intellectual powers, and their qualified doctor is a highly efficient product. It is of some interest to consider how they obtain their results and the price they pay for them.

The regulations, fixed by law, of the Swedish medical curriculum lay down the courses which must be served, as do ours. Having completed these satisfactorily, the Swedish student is entitled to take his examinations in the various subjects when and as soon as he likes. Consequently, there is no legal period which is exactly comparable with our 5 academic years, a time considerably exceeding the duration of the necessary courses. The main divisions of the Swedish curriculum closely resemble our own. Before registration as a student an examination in general education must be passed, and also an examination in chemistry and physics. These can be taken together in the State examination. This will be passed usually at the age of 18 years. The medical curriculum proper is divided into two parts, which may be referred to as Pre-clinical and Clinical. The subjects in these are practically identical with our own divisions.

With regard to the Pre-clinical Period, the legal minimum for the courses is five terms—that is, two years and four months—and the examinations can be passed in this time, though it is not easy. There is a paragraph in the regulations which states: "The estimated time for the Pre-clinical Examination is thus, according to this plan of study, 3 to 3½ years," the longer time mainly referring to students commencing in the middle of the academic year. These times are estimates, and are in no way compulsory. There is certainly no reason why students should not complete this part in not more than 3 years.

The courses in the Clinical Period are calculated not in terms but in months. These courses can be completed in 33½ months or even in 31½ months, with the overlapping allowed in certain courses, such as dermatology and ophthalmology. The total for the two parts is thus approximately 5 years. To pass the examinations and qualify actually in the minimum time would be far more difficult than qualifying in 5 years in this country; probably it is impossible, but it is said to have been accomplished in little over 5 years. At the end of sections defining the courses necessary in the clinical subjects there is an estimate of the amount of time which it is suggested is needed for additional reading. For example, the section on pathology states: "The time of study for the examination in this subject is estimated at 2 months." These times of study add up to 15 or 18 months. These are not in any way compulsory, and are not by any means always necessary.

There is a paragraph in the regulations which states: "According to this plan the estimated time of studies for the Licentiate of Medicine Examination is 4½ years after the Pre-clinical Examination." This is apparently arrived at by taking the courses at 3 years and the times of additional study at 1½ years. This is an extreme figure according to the total of times quoted, but in any case it is not compulsory. A group of students gave the estimate for the Clinical Period as "3 years, or more often 3½ years." There should be no difficulty in a Swedish student qualifying in 6½ years. This would, I think, about correspond to a student in this country qualifying in 5½ years on a five years' curriculum. As a personal opinion I should estimate the Swedish curriculum to be 9 months longer than our 5 academic years, or possibly 12 months, but not more.

The period of 8 to 9 years quoted for the curriculum is no doubt arrived at by adding the 3 to 3½ years and the 4½ years for the two parts, and possibly the extra year is added for resident hospital appointments. These, however, are not compulsory in Sweden, except for certain Government services, and a student, after passing the examinations, is fully entitled to practise, as in this country.

When a Swedish student takes 7½ or 7¾ years to qualify, it will commonly be found that he has spent 3½ years on the clinical part and 4 years or more on the pre-clinical part. The Swedish student on an average apparently wastes a year or 18 months in the Pre-clinical Period, for which he receives no appreciable return or benefit. Many students take 8, 9, 10, or more years to qualify, and it is a matter of curiosity why this occurs, since Swedes are a highly intellectual and industrious race. The explanation appears to lie in the system of examinations. As we are dissatisfied with our own system, it is interesting to observe the apparent results of a different method.

There is a separate examination in each subject—for example, ophthalmology. When a student wishes to be examined he goes to the teacher, who is always the examiner and is generally the professor, and asks for an appointment. He has a right to be examined within fourteen days, but in practice it will rarely be delayed more than forty-eight hours. The examination is a private and personal matter between the student and the professor. There are practically no rules as to how it shall be conducted. There is no written paper. The student's "examination book" is then marked for that subject "Not passed" or "Passed," or "Passed [with various commendations]." This method is clearly a considerable imposition on the professors. There will be no

pressure on students to present themselves prematurely, and the time, especially in the Pre-clinical Period, slips away easily. The percentage of rejections seems to be low.

The average time for qualification appears to be about 7½ or 7¾ years. The finished article is very good, but the long time of preparation increases its cost. It is a serious matter to put a son into the medical profession, although the subsequent return in practice is good. A doctor in ordinary practice can manage with some difficulty one son, but can scarcely afford to have two sons as medical students. Taking the number of qualified doctors per 100,000 of population, the United States has approximately 130, Canada 105, Britain 90 to 100, France and Germany 70 to 80, and Sweden 35. On an average there is a qualified doctor in this country for every 2 square miles and 1,000 inhabitants, in the United States for every 30 square miles and 800 inhabitants. The Swedish doctor is responsible for 90 square miles and 2,800 inhabitants. To accomplish his duties successfully, he needs at least to draw fully on the fine intellect, the efficient teaching, and the magnificent physique which he usually possesses.—I am, etc.,

London, W., Jan. 5th. H. LETHEBY TIDY.

OBSTETRICAL EDUCATION OF THE UNDERGRADUATE

SIR,—One must respect and sympathize with the endeavour of Professor Munro Kerr to render perfect the obstetrical education of the undergraduate and so to diminish or to abolish sepsis and trauma in midwifery cases. Unfortunately, the doctor has to look at the economic aspect. He is now asked by the experts to put in six months' training as a student, and then to serve a further year as an "intern" in one of the many hospitals for midwifery which are to spring up in the near future. It is reasonable to assume that, acting on the specialists' advice, which is to include financial pressure—for example, the proposed withholding of the maternity grant unless the confinement takes place in a hospital—the great bulk of the present "private cases" will be dealt with in institutions. The graduate, supremely educated, will emerge from his training with no work to do; economically it will be so much wasted time.

Again, all abnormal cases will be dealt with in these hospitals; the residue, if any, will be normal cases, with which any nurse can deal. There will remain a few who will insist on a doctor in addition to a nurse. Following expert instruction, the treatment of these must include a first examination of a complete and searching nature—heart, lungs, blood pressure, urine, measurement of pelvis, examination of uterus and vagina—thereafter an examination every fortnight, and for the last month, each week, tests of urine, blood pressure, etc. The treatment of anything abnormal must be included; masks, sterile outfit, and so on must be used at the confinement itself, followed by three weeks' attendance and examination in two months' time for prolapse or displacement. Supervision and correction of any abnormalities will be the routine for a year thereafter. For all the above the biggest fee obtainable here is £5 5s.!

In the public press Professor Kerr stated some months ago that "80 per cent. of all midwifery was already institutional." He said that the advocates of non-institutional maternity treatment were fighting a losing battle and that the proper place for maternity cases was the ward of a well-equipped maternity hospital. If he is right, then why should the student be robbed of a year of his life getting superlative training for work he will never do?—I am, etc.,

Dennistoun, Jan. 3rd. JAMES COOK, M.B.

THE HAEMORRHAGIC DIATHESIS AND THE ANTITRYPTIC INDEX

SIR,—Dr. Letheby Tidy, in his valuable and helpful article in your issue of December 27th, 1930, concludes that the haemorrhagic diathesis is due primarily to an increased permeability of the capillary endothelium, but he attempted no explanation of this. About 1909 I had the privilege of working with my brilliant friend Dr. E. C. Hort, who died prematurely a few years later. His doctrine, which seems in danger of oblivion, was that almost any cell in the body is capable of digesting itself, and is restrained only by the antitryptic power of the blood. Normal horse serum, especially if fresh, has the same power of inhibiting tryptic digestion; and we have all observed that, in a person dying of bleeding into the digestive canal, the blood is not at all digested although an excellent food.

Hort explained purpura or mucous haemorrhages by assuming that a subnormal antitryptic power of the blood permitted endotheliolysins or mucolysins to digest these membranes. (The platelets would then repair the breach.) As a clinician, I have found this doctrine confirmed by the apparent dramatic cure by horse serum of some cases of purpura haemorrhagica and of all (so far) of the formerly fatal cases of melaena neonatorum. But the case which really convinced me was that of a girl of 8, operated on by Mr. E. M. Hainworth for congenital hip by the bloodless method of Lorenz. About ten days afterwards she developed a septic pimple on the forearm. This rapidly became an ulcer, which spread so quickly that in a very few days it covered three-quarters of the length and circumference of the forearm. The extensor muscles were also visibly being digested away, but not the tendons. No granulations were to be seen. As I was then working on the antitryptic index, my delight may be imagined when dressings of gauze, kept moist with normal horse serum, immediately arrested this nightmare of autodigestion. Granulations quickly appeared and epithelialization was encouraged by scarlet-red ointment 8 per cent.

At the instigation of Hort I worked out an easy method of measuring the antitryptic index with only a finger-prick of blood, whereas a syringeful had previously been required (*British Medical Journal*, June 25th, 1910). Daily observations on a patient for two and a half months yielded a curve indicating that a proper dose of vaccine or tuberculin reduced the raised antitryptic index nearer to normal, and an overdose made it dive below normal. But the method is non-specific (possibly an advantage), and pathological opinion was then dominated by the specific methods of Sir Almroth Wright (opsonic index). So that Hort's doctrine and the antitryptic index were largely ignored and appear to have been undeservedly forgotten. It seems likely that they could now be applied profitably to the haemorrhagic diathesis and its etiology.—I am, etc.,

Hull, Jan. 6th. FRANK C. EVE, M.D., F.R.C.P.

TREATMENT OF ENURESIS

SIR,—At a recent meeting of "Le Carrefour de Cos" (where we discuss those medical topics that are not taught at school) Dr. Ferreyrolles of La Bourboule told us of a treatment of enuresis which has been carried on with marked success for many scores of centuries. Dr. Ferreyrolles is well-known as a learned student of Chinese medicine, and is about to issue a book on acupuncture, a treatment which aims at the starting of various reflexes by the stimulation of superficial well-defined spots. In China they use fine needles or heat. We combine both with the modern galvanocautery. In order to inhibit

the contraction reflex of the bladder, very light and short stimulation is needed. Those who are conversant with the laws of physiology will jump right to the conclusion that overstimulation would produce exactly a reverse effect.

In cases of enuresis, light stimulation (a prick, skin deep, with the fine loop of the cautery) should be applied at the base of the matrix of the big toe nail just outside the middle line on both sides. If a cure is not secured by the first attempt, or if relief does not prove to be permanent, the same procedure should be repeated. Other spots which we consider as secondary (scattered on the reflex track between toe and spine) have been mapped out by the Chinese.

If I venture to suggest in our Near West this Far East method it is because we have had results amazingly—and to my sceptical turn of mind quite unexpectedly—satisfactory. The best testimonials are to be found in the letters of those who have tried it. Everything that is new is not always good, nor is everything good always new.—I am, etc.,

GUSTAVE MONOD, M.D., M.R.C.P.

Vichy, Jan. 5th.

GLYCERIN AS A SURGICAL DRESSING

SIR,—I am interested to see in Dr. D. Kyle's letter in the *Journal* of January 10th a reference to a letter of mine of 1909. I write now, however, because it does seem that Dr. Kyle mistrusts the hygroscopic action of glycerin, whereas I have always maintained, and still do, that it is that action which is the essence of its success. Indeed, I once protested, in referring to the magnesium sulphate paste of Sir Almroth Wright, that he and I equally caused a centrifugal stream of lymph, and so interfered with the centripetal tendency of septic organisms; but whereas Sir Almroth Wright kept his germs alive in the non-bactericidal paste I killed mine in the carbolic acid.

Carrying that theory to its rational end, I used the *B.P.* carbolic acid solution of 1 in 5, so that the germs, when drawn out of the lymphatics by the glycerin, should find themselves in a pool of carbolic acid sufficiently strong to destroy them. Of course, glycerin is an alcohol, and may well act as a bactericide; but I had neither means nor leisure to determine its efficiency therefore I took no risks. Dr. Kyle's work strongly suggests that glycerin is sufficiently potent by itself.—I am, etc.,

London, E.C.2, Jan. 10th. A. OGIER WARD.

PROPHYLAXIS IN MIDWIFERY

SIR,—I am grateful to you for giving me an opportunity of thanking those who have so kindly written to me, following my letter in the *British Medical Journal* of December 20th, 1930 (p. 1066), on the above subject, and asking for further information about the methods suggested.

I have been in communication with Dr. W. H. Martindale as to the simplest method of preparing the flavine and glycerin, and we recommend the following method. Heat 4 oz. of glycerin to 110°-C. for five minutes, allow to cool a little, then add one tablet acriflavine 1.75 grains (British Drug Houses), previously powdered. This will make a 1 in 1,000 solution ready for vaginal injection. The tablet must be powdered before adding to the glycerin, as it dissolves instantly and does not require prolonged heating, which would decompose the glycerin. Flavine has been selected on the advice of Professor Oldfield of Leeds. It has the following advantages: it possesses an extremely high antiseptic power, it is not toxic to the tissues, it is practically non-irritant even to mucous tissues in dilutions at which it is highly toxic to pathogenic bacteria, and, last, but by no means least, it is highly toxic to the gonococcus.

In the latter part of my letter I advised the continuous administration of calcium salts; this also is an important prophylactic measure. In my paper written two years ago I advised the continuous administration of calcium salts during pregnancy for the *prevention* of the two great toxaemias of pregnancy—pernicious vomiting and albuminuria and eclampsia; these conditions are *more closely allied than was at one time thought* to be the case. I recommend, as soon as pregnancy is suspected, the administration of calcium phosphate 15 grains in half an ounce of water thrice daily, and in addition two glasses of milk a day, plenty of fresh fruit, and green vegetables, together with carbohydrates, and a diet of fish, eggs, chicken, etc., with a minimum of meat, or preferably no meat at all; the urine to be examined each fortnight at the first sign of albumin, the calcium phosphate to be taken three-hourly, and the patient given milk ad lib. (more calcium), fresh fruit, and green vegetables, and to be kept on this treatment till the albumin disappears. At the first sign of pre-eclamptic symptoms an intravenous injection of calcium chloride to be given, as recommended by J. L. Wodon.

There are several curious well-known facts in connexion with eclampsia that seem to confirm my theory that calcium therapy is *the* prophylactic remedy for it.

1. There is a seasonal variation in the calcium content, the highest percentage being during the months of maximum sunshine. Harrar of New York considers that the increased incidence of eclampsia in the early spring is due to the cold and damp weather. It is curious that this phenomenon should occur at a time when the calcium content is low.

2. The incidence of eclampsia is much less in warm countries than in cold. May not the increased calcium content, due to the presence of more sunshine, be the cause of this?

3. There was a startling reduction in the incidence of eclampsia in Central Europe during the great war, and after the war the incidence reverted to pre-war figures. This has been ascribed to various causes. As the diet was restricted in fats and meat, it is probable that more milk and fresh vegetables were taken. The lowered incidence has been ascribed by some observers to the ingestion of more fresh vegetables. Is it not possible that the increased consumption of milk (calcium) and the increased consumption of fresh vegetables and fruit containing vitamin C, which is associated with the metabolism of calcium, were the cause of the startling reduction in the incidence of eclampsia?

I am also of opinion that the continuous administration of large doses of calcium is of great benefit in those cases of lowered resistance where the patient falls an easy prey to infection from within or without.

I only ask that a reasonable trial be given to these methods, and that they be judged after a fair trial has been given them, and not before.—I am, etc.,

Congleton, Jan. 6th. J. L. MOIR, M.B., Ch.B.

GENERAL PRACTITIONERS AND ANTE-NATAL WORK

SIR,—In a lecture by Dr. W. H. F. Oxley on the role of the general practitioner in ante-natal work, reported in your issue of January 3rd, there is a reference (p. 6) to the arrangements in this county which may possibly result in misunderstanding. It is an essential part of the Hampshire scheme that a woman unable to attend one of the ante-natal clinics can be seen by the general practitioner chosen at her home or at his surgery, whichever he considers preferable. I regret that I was unable to be present at the opening of Dr. Oxley's most interesting lecture, or I should have taken the opportunity of pointing this out.—I am, etc.,

H. LESLIE CRONK,

Winchester, Jan. 8th. *County Medical Officer, Hampshire.*

ECLAMPSIA WITH UNUSUAL SYMPTOMS

SIR,—In the *Journal* of November 29th, 1930, there is a report of a case of eclampsia with unusual symptoms by Dr. H. R. Sparrow, which concludes with the remark: "Unfortunately we have no answer to the question, What would have happened if hospital treatment had been adopted on May 30th?" Perhaps the history of the following rather similar case may go some way towards a solution.

A primipara, aged 27, had, on account of having suffered from pyelitis some three years previously, been kept under particularly careful supervision and the urine frequently examined. Up to September 17th everything had been perfectly normal, and her general health throughout her pregnancy had been excellent. On that date a trace of albumin was found in the urine, and there was some slight oedema of the ankles. The blood pressure was 150/100. She was immediately sent to hospital and put on a fluid salt-free diet, with diuretics and saline purgation. By the next day (18th) the oedema had gone, and did not return; there was no headache, and the albumin was about the same. Between this and the 22nd she felt absolutely well, was passing urine copiously, and the blood pressure had fallen to 135/90. There was, however, some slight increase in the amount of albumin. On the 22nd, labour commenced in the early morning; at 6 a.m. she vomited some bile, but apart from the pains felt well. At 1 p.m. she was delivered of a 6½ lb. child, the placenta following in fifteen minutes, with a normal loss. During the afternoon she twice vomited some more bile, but felt quite cheerful. At 9.15 p.m. she complained of increasing epigastric pain, and, this being so frequently the precursor of convulsions, she was given 1/4 grain of morphine hypodermically. In spite of this a convulsion began at 10 p.m., and lasted about ten minutes, consciousness returning about 10.20. This was the only convulsion she had, and she remained conscious to the end.

The next day (September 23rd) the urine was scanty, and still contained about the same amount of albumin, but she was perspiring freely; blood pressure 125. Beyond feeling rather weak, she made no particular complaint. Towards evening jaundice began to appear, but liver dullness seemed quite normal, and there was no return of the oedema. On the morning of the 24th the abdomen was distended, and while this was somewhat reduced, following a high enema, it later returned. The urine was still scanty, blood pressure 110, and weakness more pronounced. She complained of being very tired, and died at 2.30 p.m. Permission for a necropsy could not be obtained.

In many ways this case closely resembles that of Dr. Sparrow: the comparatively small amount of urine, the falling blood pressure (at no time excessively high) without amelioration of the condition, and the absence of oedema.—I am, etc.,

J. B. MACKAY, M.B., Ch.B.

Provost, Alberta, Dec. 19th, 1930.

ACCESSORY LOBE OF AZYGOS VEIN

SIR,—With reference to the very interesting article on the accessory lobe of the azygos vein, by Drs. H. P. Nelson and George Simon, in the *Journal* of January 3rd, I wish to report that I have a film of this condition identical with Figure 3 (p. 10). It is of a boy, aged 12, and was taken in April, 1930. The film is No. 1721 in our series of films of patients in this department, and so far is the only one of the condition I have had.—I am, etc.,

GEORGE HURRELL, M.D.,
Tuberculosis Medical Officer,
Newcastle-upon-Tyne.

January 9th.

THE MEDICAL CHARITIES

SIR,—I am wholly with Dr. Claude Wilson in his plea for better support of the medical charities by the profession. For two years consecutively you have allowed me to recommend in your columns one particular kind of such support—namely, by testamentary bequest. I had meant to refrain this January; but Dr. Wilson's letter encourages me to mount my hobby-horse once more. A year ago I began to make a collection of cuttings from the *Times* of bequests to charities by medical men, to whom every kind of beneficent organization seemed to be dear, except the two great charities of their own profession. But the cuttings multiplied so quickly that I got disheartened and threw them away. Seriously, Sir, it is very strange that of those of our colleagues whose estates are more than sufficient to provide for their dependants so few ever bear in mind the Benevolent Fund and Epsom College. The former has, I fancy, been notified of one really useful windfall during the past year; the latter, as your own columns have recently told us, needs £18,000 to complete the new sanatorium, a debt which must be as a millstone round the neck of the council unless some valuable legacy should eventuate. Both institutions should be much more frequently and liberally helped by testamentary dispositions than they are, as well as by the increased subscription income which Dr. Wilson calls for.—I am, etc.,

London, S.W.5, Jan. 5th. HENRY ROBINSON.

Obituary

JOHN JENKINS, M.R.C.S., L.R.C.P.

Medical Superintendent, Hammersmith Hospital

Dr. John Jenkins, who died at Hammersmith Hospital on January 3rd, was born in 1869, and received his medical education at University College, Cardiff, and University College, London, where he qualified as M.R.C.S., L.R.C.P. in 1902.

Mr. SIDNEY FORSDIKE writes: After a short experience of mental work at Colney Hatch and Hanwell Asylums, Jenkins became assistant medical officer to Dr. Thackray Parsons at Fulham Infirmary. He carried out his duties so well that when the present Hammersmith Hospital was opened in 1905 he was appointed its first medical superintendent, a post which he held with signal success to the day of his death. During the war the hospital was taken over by the War Office as an orthopaedic centre, and Jenkins, as the officer in charge, was given the rank of major. He was later appointed president of the Military Invaliding Boards, holding office until peace was proclaimed. When the War Office vacated the building it was reconditioned and rehabilitated under his supervision. He was of small physique, and his friends regarded him as a Class A man from the point of view of health, but to their astonishment and grief he was carried off in the space of thirty-six hours after a brief but tragic illness. He was a man of great character and tact, which was the secret of his successful administration of a large hospital. He was rather reserved, and did not make friends readily, but once within the defences a loyal and generous nature was revealed. He was ever ready to help the weak and the deserving, but had little patience with the wastrel. To all at Hammersmith he was "the chief," well beloved and respected, an esteem which was shown by the numbers who took a last farewell glance at him as he lay dead, and by the enormous attendance at a memorial service held in the chapel of the hospital on January 7th, the day of the funeral. On his last journey, to Golders Green Crematorium, he was escorted by his immediate medical staff and his oldest friends, among whom I am privileged to be one. He is survived by his widow.

Dr. C. THACKRAY PARSONS writes: It was my privilege to know Dr. John Jenkins from December, 1902, when he came to Fulham Infirmary as assistant medical superintendent, until his sudden death early this month. Promoted to the medical superintendentship of Hammersmith

Hospital at its opening in 1905, he gave the whole of the rest of his life to its service. The improvement of it, the maintenance of it in the front rank of the London Poor Law infirmaries, absorbed him. He wore himself out by his devotion to it. In a short time of consciousness, nine hours before his death, he said, "I can't think why you are making this fuss about me; I am not going to stay in bed; I shall get up to-morrow and get back to work." He was a great administrator. He knew how to get the best out of his staff, to stimulate them in their work, and to maintain a strict discipline whilst retaining their affection. His was a full life. Work-time and leisure time he filled with interest. He read widely and with discrimination. He was a good shot; and, being interested in all mechanical things, motoring was one of his great joys. With his genius for friendship he had a wide circle of friends, and bound them to him by his sympathy and practical advice and help in difficulties. Married in 1905, no man was more fortunate in his wife. They were never apart from the day of their marriage, and were one in thought, interests, and aims. We who knew him know how much he owed to her in times of stress and in times of peace. "The buisy world is hushed, the fever of Life is over." "Mori est felicis antequam mortem invocet."

MAURICE FITZMAURICE-KELLY, F.R.C.S.

Assistant Surgeon, Royal Sussex County Hospital

The medical profession of Sussex has suffered a great loss by the death, at the age of 52, at a nursing home in Hove, of Mr. Maurice Fitzmaurice-Kelly. He received his medical training at St. Mary's Hospital, London, and won the gold medal in surgery at the London University, graduating M.B. in 1902, and obtaining the B.S. and F.R.C.S. in 1905. During the first week of the war he joined the R.A.M.C., and was sent to Antwerp, but his ship arriving on the coast of Belgium after the fall of that city, he landed a fortnight later at Boulogne, and became attached to the 13th General Hospital, which he largely helped to equip. He afterwards became surgical specialist at Calais, and was there under canvas during the very severe winter of 1916–17. He was also for a short period at a casualty clearing station, and the illness from which he died dates from the exposure he suffered during that winter. He was invalided home as a stretcher case about six months before the end of the war, and was still in hospital on November 11th, 1918. Shortly afterwards he was sent down to Brighton on account of his health, and was offered the post of chief of the surgical wards of the Pavilion, which he accepted, remaining there until the closing of that building as a hospital. During this period he was also attached to the Ministry of Pensions Hospital at Shepherd's Bush, and to Queen Mary's Auxiliary Hospital at Roehampton.

On completion of his war service, Mr. Fitzmaurice-Kelly remained in Brighton as a consultant, and was appointed surgeon to the Royal Alexandra Hospital for Sick Children (from which, for reasons of health, he resigned last year), to the Hove Hospital, and, later on, assistant surgeon to the Royal Sussex County Hospital. He was an active member of the Brighton Division of the British Medical Association, at which he frequently showed his cases at clinical meetings, and of the Brighton and Sussex Medico-Chirurgical Society. He was a man of outstanding ability, was held in the greatest esteem by his professional colleagues, was a most brilliant operator, and devised many modifications of operative technique, notably for amputations at the hip-joint, his method being described in Carson's *Modern Operative Surgery* as the best one in use. He leaves a widow and four children.

Dr. L. A. PARRY, honorary secretary of the Sussex Branch, writes: I have known Fitzmaurice-Kelly ever since he came to Brighton, and saw a good deal of his work, both in private and at the Children's Hospital. He was a regular attendant at the clinical meetings arranged by the Brighton Division of our Association, frequently showing cases and demonstrating some novel and skilful operation he had employed. He threw his whole heart into his profession. His work at the Children's Hospital and at the Royal Sussex County Hospital was always carried out with the greatest enthusiasm; no case was too much trouble, all presented something of interest to him; nothing was left undone by him for his patients. He went meticulously into every detail which would help them towards recovery. We have lost a very brilliant surgeon and a good colleague.

The death of Dr. RICHARD BRODIE, school medical officer for Ross and Cromarty, occurred suddenly at his home in Maryburgh, Ross-shire, on New Year's Eve. Both for his personal qualities and for his outstanding efficiency in his public health work, he will be greatly missed by the county, which three weeks before sustained another tragic loss in Dr. William McLean, the medical officer of health. McLean and Brodie were brothers-in-law, and were united by ties of friendship and of close official associations. It was difficult to think of the one without the other. After graduation in Edinburgh in 1898, Dr. Brodie became parish medical officer at Munlochy in the Black Isle district of Ross-shire. He practised there for many years, and was successful and popular among his patients. The war came, and to his temperament the attraction of serving was irresistible, although he could ill be spared. He was attached to a territorial battalion of the Seaforth Highlanders, with which he went out to France. He was invalided home, and later was medical officer in charge of the hospital at Cromarty, an important station throughout the whole of the war period. Brodie discharged his duties with the greatest acceptance. At the end of the war there was need for a medical officer to take charge of the inspection of school children of the county, and Brodie was appointed. For ten years he laboured with the greatest zeal, and built up a most efficient service. As in everything else he undertook, his humour, friendliness, and personal charm smoothed the official path. His years in practice had given him a wide outlook, together with experience desirable in an adviser of school children, and all over the county he was received with great respect and affection. His military funeral was attended by members of the 4th and 5th Battalions of the Seaforths, and by a great number of official and private friends.

Through the untimely death of Miss AMY HODGSON, M.D., M.R.C.P., the medical profession has lost a member of an admirable type. The leading motive that influenced her in embracing her vocation was service. Dr. S. G. Moore, lately M.O.H. for Huddersfield, writes: Endowed with mental qualities above the average and many other virtues, the amelioration of the lot of the young gave to Dr. Hodgson a natural outlet. Her contributions to current medical literature are evidence of this intention. Thus, "Vitamins and rickets," "Comparative results of child welfare work," "Milk and child welfare," are all worthy of serious consideration. An advertisement for a medical officer to conduct a special intensive scheme of work for the reduction of infant mortality in Huddersfield attracted her, and she received the appointment. During a complete year of work the infant mortality figure fell from 75 in the preceding year to 48, surely a notable reduction. Dr. Hodgson achieved success in a difficult part of the task, one which is essential: she secured the confidence of the mothers, and of the grandmothers also, to a remarkable extent. This was not merely due to competence as a physician and a paediatrician, nor to keenness on the task, nor to mere

kindliness and sincerity. Dr. Hodgson brought all these factors into play; but in addition there were authority, and an earnestness born of a consciousness of the importance of the subject, which were of at least equal consequence. The excellent work of the Infants Hospital in Vincent Square next attracted her. She secured a post on the staff and did admirable work there under the direction of Dr. Eric Pritchard, until the time came when she felt justified in practising as a consultant paediatrician. She took rooms in Harley Street, and worked there until serious illness interfered. General professional regret for the cutting short of such a career is accentuated by many memories of a charming personality considered from the purely social side.

BRITISH EMPIRE CANCER CAMPAIGN

At the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held on January 12th, with Sir CHARLES GORDON-WATSON in the chair, a grant of £6,000 was made to the Middlesex Hospital towards the maintenance of its cancer research work for the year 1930-31, and a further grant of £600 (making a total of £3,600 since 1925) was authorized to the cancer research committee of the Marie Curie Hospital, for the services of its medical research officer.

Sir Cuthbert Wallace, director of the Radium Institute, London, was elected a member of the Grand Council and, in view of the importance attached by the Campaign to the study of comparative medicine and pathology, Professor F. T. G. Hobday, principal of the Royal Veterinary College, was invited to become a member of the Grand Council.

Approval was given to the arrangements proposed for examiners and judges in connexion with the Garton Prize of £500 and gold medal, to be awarded for the best original dissertation on "The early diagnosis of cancer" submitted by December, 1931. "The biological effects and mode of action of radiations upon malignant and other cells" has been chosen as the subject for the second award, dissertations for which must be received by December, 1933.

It was reported that the popular handbook *The Truth about Cancer*, issued to the public on December 4th, 1930, was now obtainable from all booksellers, or direct from the publishers, Messrs. John Murray, at 2s. 6d. a copy, and that it had been received with appreciation in all directions. It is intended to issue revised editions from time to time in order to keep the book abreast of all developments in connexion with the cancer problem.

The Grand Council appointed the Saskatchewan Cancer Commission a branch of the Campaign, thus completing representation in New Zealand, the States of Australia, the Union of South Africa, and Canada. A communication was read from the Queensland branch expressing appreciation of the technical advice accorded it in connexion with the proposed establishment of a radon centre in Brisbane.

Universities and Colleges

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

Professor E. P. Cathcart, regius professor of physiology in the University of Glasgow, will give two lectures on the national diet, with lantern illustrations, on February 23rd and 24th, at 6 p.m. The chair at the first lecture will be taken by Sir Walter M. Fletcher, secretary of the Medical Research Council. Admission is free without ticket.

KING'S COLLEGE

Three lectures, entitled "The constancy of the internal environment: its evolution and purpose," will be delivered at King's College, Strand, W.C.2, by Professor Joseph Barcroft, on Mondays, January 26th, and February 2nd and 9th, at 5.30 p.m. The lectures, which will be illustrated by lantern slides, are addressed to students of the University and others interested in the subject. Admission is free without ticket. Dr. H. H. Dale, director of the National Institute for Medical Research, will take the chair at the first lecture.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the undermentioned examination:

D.P.H.—E. Hughes, J. W. Pickup.

UNIVERSITY OF BRISTOL

The Markham Skerritt Memorial Prize is available for award this year. It is open to the medical member of the University of Bristol (not a member of the medical board for the time being) who, in the opinion of the board, has in the three previous years published the best original work in any branch of medical science. Applications should be sent to the Dean of the Medical Faculty.

NATIONAL UNIVERSITY OF IRELAND

At University College, Dublin, on January 10th, the following degrees in the Faculty of Medicine were conferred by Dr. Denis J. Coffey, the Vice-Chancellor:

M.D.—M. J. Bryson, V. C. Ellis, F. L. McLaughlin, M. J. O'Neill.
M.Ch. (*Ophthalmology*).—F. J. Lavery.
M.B., B.Ch., B.A.O.—M. Moriarty, F. O'K. Craven, C. P. B. Bermingham, L. Dunne, P. Dunphy, J. J. Groome, M. J. C. Lynch, N. J. McGahon, P. A. McGuinness, T. J. Martin, T. A. Moynihan, P. O'Driscoll, Johanna O'Shea.
D.P.H.—P. J. Deery, M. M. J. Maughan, J. C. A. Liddy, J. O'Gorman, Margaret M. Partridge.

Dr. Thomas Walsh, professor of pathology, University College, Cork, has been appointed to represent the University at the annual conference of the National Association for the Prevention of Tuberculosis at Margate in June.

UNIVERSITY OF GLASGOW

The Harry Stewart Hutchison Prize, of the value of about £50, will be awarded in 1931 for the best writing embodying original research work in a branch of medical science relating to children. Medical graduates of not more than ten years' standing from the date of first graduation in medicine, of all British home and colonial universities, are eligible. Compositions, distinguished by two mottoes, must be sent to the Clerk of the Senate, University of Glasgow, by March 31st, accompanied by a sealed letter bearing upon the outside the same mottoes and containing a declaration by the author that the composition is entirely his own.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following course of lectures will be given in the College at 5 p.m. during the next three weeks. January 19th: Professor Victor Bonney, results and technique of myomectomy; January 21st: Professor J. Basil Hume, pathology of diaphragmatic hernia; January 23rd: Professor J. W. Tudor Thomas, successful grafting of the cornea in rabbits; January 26th: Professor D. H. Patey: the pathological basis for the treatment of varicose veins by injections and its bearing on the problems of thrombosis; January 28th: Professor J. Paterson Ross, treatment of cerebral tumours with radium, with an account of experiments made to study the effects of radium upon cerebral tissue; January 30th: Dr. Donald Hunter, changes in the bones in hyperparathyroidism and hyperthyroidism; February 2nd: Mr. H. H. Woollard, the potency of pharyngeal entoderm; February 4th: Mr. T. P. Dunhill, malignant disease of the thyroid gland.

COUNCIL MEETING

A quarterly Council meeting was held on January 8th, when the President, Lord Moynihan, was in the chair.

Mr. Russell J. Howard, Mr. E. C. Hughes, and Mr. L. E. C. Norbury were introduced and admitted Members of the Court of Examiners.

Diplomas

Diplomas of Membership were granted to Mr. S. S. Ahluwalia, Mr. W. N. Chalmers, and Mr. E. M. Sharples, who have complied with the by-laws of the College.

Diplomas in Psychological Medicine and in Laryngology and Otology were granted jointly with the Royal College of Physicians to twelve and eleven candidates respectively.

Fellowship Examinations

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship stating that at the examination held in December, 1930, 178 candidates were examined, of whom 57 were approved and 121 rejected.

The Secretary reported that arrangements have now been made for Professors Wright and Buckmaster to conduct a primary examination for the Fellowship in Australia, at Melbourne, on August 11th, 1931, and following days, and in Canada, at Toronto, on October 20th and following days.

Appointments

The President reported that Mr. Wilfred Trotter had been appointed Hunterian Orator for 1932, and Mr. W. Sampson Handley Bradshaw Lecturer for the ensuing year.

Mr. J. H. Thompson, lecturer in physiology under Professor McDowall of King's College, was appointed Meldrum Research Scholar for one year, the subject of his research to be

"Investigation into the influence of the parathyroid gland on processes of growth."

The Hallett Prize was awarded to Jack Carl Rudolph Hindenbach of the University of Otago, New Zealand.

Lord Moynihan was appointed delegate to the centenary meeting of the British Association, to be held in London on September 23rd to 30th, 1931.

Representation of Members on the Council

The Council of the College gave the following answer to the resolution of the annual meeting of Fellows and Members:

"The main functions of the College are to promote and encourage the art and science of surgery for the common weal, and for this purpose to conduct the examinations of the College and to maintain the great Museum and Library placed under its care. In carrying out these functions the Council organizes lectures and demonstrations, provides facilities for, and encourages research, fosters social intercourse and the amenities of the profession, and in every way possible renders the College an instrument for the advancement of surgery in its widest sense, not only for the benefit of the Members and Fellows, but the whole profession throughout the Empire. In the opinion of the Council these functions are well carried out under the present constitution: after further and prolonged deliberation the Council has therefore decided that it is not desirable to alter the constitution of the College by providing for the direct and separate representation of Members of the College upon the Council. The decision of the Council is in conformity with the opinion expressed three years ago by the body of Fellows of the College, who are the electorate."

Medico-Legal

MARKING OF SURGICAL INSTRUMENTS

PROSECUTION UNDER MERCHANDISE MARKS ACT

At the Marylebone police court on January 9th, before Mr. Hay Halkett, Van Lier Brothers, Limited, of Eden Street, N.W., vendors of surgical instruments, were summoned to answer three charges under the Merchandise Marks Act, 1926. The Board of Trade prosecuted on information given by certain firms of instrument manufacturers. It was alleged that the firm had advertised and offered for sale under a specific designation certain imported surgical instruments of a class or description to which an Order in Council under the Merchandise Marks Act, 1926, applied, and did not include in the advertisement an indication of the origin of the goods; further, that they sold in the United Kingdom imported surgical instruments made solely or mainly of metal which did not bear an indication of origin as defined by the Merchandise Marks Act.

Mr. G. B. McClure, who appeared for the Board of Trade, explained that under an Imported Goods Order, 1928, surgical instruments of foreign make, when sold in this country, must be so marked in one of various specified ways. He put in a catalogue entitled "'Summit' stainless surgical instruments," issued in November, 1930, which gave no indication that any of the goods described were foreign made. He also presented a number of instruments which bore the trade mark "Summit" and the word "foreign" as evidence that the defendant company knew of the requirements of the Act. Moreover, he said, one of the firms which had laid the information made a habit of printing on their invoices a warning that all goods made abroad must be so marked.

Mr. G. D. Roberts, for the defendant firm, entered a plea of guilty. He pointed out, however, that the law was not quite as simple as Mr. McClure had stated. The Act declared that it was illegal to sell or expose for sale any imported goods to which any name or trade mark was applied, unless the trade mark was accompanied by an indication of their origin. The defendant company was not charged under that section, and had never infringed it. The catalogue upon which the prosecution was based had been printed in 1927 before the Order was made, and had, by the oversight of a clerk, been forwarded to one of the informing firms in response to a request. The defendant company were wholesale dealers, describing themselves as surgical instrument exporters and importers. A section of the Act (Section 10 (4) (*b*)) laid it down that exposure for sale should not include exposure for sale wholesale by a person being a wholesale dealer. The wholesale dealer who exposed his goods for sale wholesale need not give any indication of origin, but when he sold the goods he must give such indication. The offence consisted in the sale to the informing firm of goods not described in the catalogue as foreign. Every article which bore the word "Summit" was also stamped with the word "foreign"; the defendants traded frankly under a Dutch name, and no deceit nor any attempt to deceive had ever been alleged. Both the prosecuting firms had accounts with the defendant firm, and both had full knowledge of the origin of the goods. The defendants exceedingly regretted that they had lost their way in the maze of this complicated legislation.

Mr. Van Lier, in evidence on his own behalf, stated that a new catalogue complying with the law was to be issued shortly. He had been unaware that the 1927 catalogue infringed the Order which came into force in 1929.

The magistrate remarked that laymen were supposed to understand everything, including matters which puzzled lawyers, such as the difference between selling and exposure for sale. The present offence was the most venial infringement of the Act which he had yet tried. There had been no serious intention to defraud. He imposed a fine of 40s. on each of the informations, and ordered the defendant firm to pay ten guineas costs.

The Services

DEATHS IN THE SERVICES

Colonel Edgar Elkins Powell, D.S.O., late R.A.M.C., died suddenly in London on December 12th, 1930, aged 66. He was born at Guildford on November 3rd, 1864, and was educated at St. George's, taking the M.R.C.S. and L.R.C.P.Lond. in 1887, and the M.D.Brux., with honours, in 1888. After filling the post of assistant resident medical officer at the Royal National Hospital for Consumption, Ventnor, he entered the Navy as surgeon in 1889, but resigned his commission in the following year. He then entered the Army as surgeon on January 31st, 1891, becoming major after twelve years' service, lieutenant-colonel on September 26th, 1916, and finally brevet colonel on January 1st, 1919, retiring on November 3rd, 1921. He served in the Chitral campaign on the North-West Frontier of India in 1895, with the relief force, receiving the frontier medal with a clasp; in the South African war in 1900-2, taking part in operations in the Transvaal, Cape Colony, and Orange River Colony, including the actions at Venterskroon, Lindley, and Rhenoster River, and gained the Queen's medal with three clasps and the King's medal with two clasps; and in the war of 1914-18, when he commanded the 24th Stationary Hospital, and, later, was A.D.M.S. of the 75th Division, in the Egyptian Expeditionary Force, was mentioned in dispatches in the *London Gazette* of January 12th, 1918, and received the D.S.O.

Lieut.-Colonel Raymond Herbert Price, I.M.S. (ret.), died in India on September 25th, 1930, aged 62. He was born on September 23rd, 1868, the son of Dr. A. G. Price, civil surgeon of Betul, in the Central Provinces, and was educated at Edinburgh University, where he graduated as M.B. and C.M. in 1893, subsequently taking the F.R.C.S.Ed. in 1907, and the D.T.M., with distinction, in the London School in 1912. Entering the new Indian Medical Service, the General List service, in the first batch gazetted, as surgeon lieutenant, on January 28th, 1897, he became lieutenant-colonel on July 29th, 1916, and retired on February 13th, 1922. He served on the North-West Frontier of India, in the campaigns of 1897-98, in the operations on the Samana Range, and in the Kurram Valley (medal with two clasps), in Tirah (clasp), and in the operations against the Para Chamkani tribe in 1899; in the Nandi campaign of 1905-6 (medal with clasp); and in the war of 1914-18: in Egypt, 1915; in Macedonia, 1915-16; with the Egyptian Expeditionary Force, in 1916-17; and in Persia and the Persian Gulf, in 1918-19.

Lieut.-Colonel Arthur Gwyther, Bengal Medical Service (ret.), died at Guildford on October 28th, 1930, aged 60. He was born at Mhow on April 16th, 1870, and was educated at Edinburgh, where he graduated as M.B. and C.M. in 1893. Entering the Indian Medical Service as surgeon lieutenant on January 29th, 1895, he became lieutenant-colonel on July 29th, 1914, and retired on January 29th, 1918. He served in the Tirah campaign of 1897-98, on the North-West Frontier of India, receiving the frontier medal with a clasp. Most of his service was spent in civil employ in Bengal. He received the Kaisar-i-Hind medal of the first class in the King's Durbar list of honours on December 11th, 1911.

Medical News

At a meeting of the Royal Sanitary Institute, to be held at 90, Buckingham Palace Road, S.W., on Tuesday, February 10th, a discussion on recent methods of sewage treatment will be opened by Dr. William Butler, senior medical officer, London County Council. The chair will be taken at 6 p.m. by Professor A. Bostock Hill.

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, January 22nd, at 8.30 p.m. Dr. Nathan Raw will read a paper on the coroner's verdict in cases of suicide, which will be followed by a discussion.

The Harveian Society of London was founded in 1831, and is therefore now entering its centenary year. At the annual general meeting, held on January 8th, Sir Thomas Horder, Bt., was elected president, Dr. G. de B. Turtle treasurer, and Mr. Cecil P. G. Wakeley and Dr. R. Cove-Smith secretaries for the ensuing session.

A conversazione and cinematograph exhibition, for members of the University of London Medical Graduates Society, will be held on the afternoon of Thursday, January 22nd, at the Eastman Dental Clinic, Royal Free Hospital, Gray's Inn Road, W.C.

The annual meeting of the Royal Microscopical Society will be held in the Hastings Hall, British Medical Association House, Tavistock Square, W.C., on Wednesday, January 21st, at 5.30 p.m. Professor R. Ruggles Gates will deliver his presidential address on "Adaptations in cellular structure."

At a meeting of the London Clinical Society at the London Temperance Hospital on Tuesday, January 20th, at 9 p.m., Dr. Geoffrey Evans will open a discussion on the importance of diet in health and disease.

The Joint Tuberculosis Council has arranged a post-graduate course in tuberculosis, to be held at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E., from February 16th to 20th, inclusive. Lectures and demonstrations will be given each morning and afternoon by members of the hospital staff. There will also be lectures on genito-urinary tuberculosis and tuberculosis of the skin at the London Hospital on February 18th and 19th, and on February 21st a lecture at the National Dental Hospital on disease of the teeth in relation to tuberculosis. Inquiries about the course should be addressed to the honorary secretary, Dr. William Brand, 8, Highway Court, Beaconsfield, Bucks.

The fourth conference of the German Association for the Investigation of Diseases of the Circulation will be held at Breslau on March 9th and 10th. Dr. O. Krayer of Berlin will discuss the theoretical basis of the action of digitalis, and Professor H. Pribram of Prague will deal with the therapeutic indications of this drug. Professor H. Schäffer of Breslau will consider the arguments for and against the employment of maximal doses. Further information may be obtained from Dr. Bruno Kisch, Lindenthal, Lindenburg, Cologne.

On the proposal of the Spanish Government the Council of the League of Nations decided in September to summon a conference on rural hygiene, to meet on April 22nd next, under the League's auspices, and to include representatives of all European States. The preparatory committee is composed of Dr. Pittaluga (Spain), Dr. Carriere (Switzerland), Dr. Chodzko (Poland), Dr. Hamel (Germany), Dr. Lutrario (Italy), Professor Madsen (Denmark), and Dr. Stampar (Jugoslavia).

The number of hospitals maintained by estates in the Federated Malay States during 1929 was 172, of which many were group hospitals, each serving several estates; 11 were in charge of resident medical practitioners. Considerable progress is reported in organizing uniformity of service by private medical practitioners on estates throughout the Federation, and hospitals are being provided or extended in order to ensure medical treatment of labourers in need of it.

An illustrated pamphlet on *Vegetables, their Use, Abuse, and Neglect*, by Mr. Charles E. Hecht, is issued by the Food Education Society, 29, Gordon Square, W.C.1, post free 3½d.

The Italian State Railways' Official Agency in London (16, Waterloo Place, S.W.1) informs us that as a result of the reduction in the cost of living in Italy (including food and house rents) it has been possible to make a general reduction in hotel tariffs of 10 per cent. The terms are now among the lowest in Europe. Special railway tickets at reduced rates are in force to Rome, the Naples Riviera, Sicily, and Tripoli (N. Africa); for example, for the journey of 2,100 miles from the Italian frontier to Sicily and back the fares are £5 14s. first class should intimate this.

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been prepared and will be ready shortly; they will not, however, be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Treatment of Syphilis

Dr. A. L. PIRRIE writes: Can any reader give me help with the following? A healthy young man, aged 23, came to me with a hard chancre on the glans penis. This was clinically confirmed by a skin specialist. Dark-ground illumination was negative, but the Wassermann reaction was positive, and novarsenobillon was given in seven intravenous doses, as is usual, 0.3 gram to 0.6 gram. The patient was given mercury by inunction and mist. hydrarg. iod. by the mouth. One month after the course he came back with glossitis, and looked ill. The *novarsenobillon* was again given, the Wassermann reaction proving to be strongly positive. He then had a course of seven 0.6-gram doses, after which the blood was again positive. A further course of ten 0.6-gram doses followed, together with intramuscular bismostab, ten 0.2-gram doses. To-day, after a month's interval, the blood Wassermann reaction is strongly positive. During treatment he has abstained from alcohol, has played golf, and has felt in the best of health. Can anything further be done? Expense does not matter.

Remission of Symptoms in Pyloric Cancer

"T. L. P." writes in reply to "Wicklow" (September 13th, 1930, p. 455): The remission may be due to the cod-liver oil acting beneficially on the septic condition, to which the cachexia of malignant disease is due in great part. It is the vitamin A content of the oil that is the influencing factor. It may be that the disease is even arrested temporarily by the improving of the patient's general resistance. In Gerson's diet, which has been recommended for lupus and cases of surgical tuberculosis, a specially high vitamin content cod-liver oil has been advocated, together with exclusion of chlorides from the food. Further, meat is allowed only twice a week, and fresh fruit, salads with raw turnips, carrots, beet, and tomato, with eggs, milk, and farinaceous foods in small quantity, and wholemeal bread. This diet has resulted in great improvement of the condition for which it has been tried. There may be the mechanical factor here, which has a tonic and vitalizing effect on the mucous membrane of the alimentary tract; and the bulk of food may act similarly on the musculature of the system; thus a too rapid absorption of the stomach contents or those of the duodenum into the blood stream is avoided. In this case septic and toxic products on the surface of chronic or malignant ulcers will be excluded from the blood stream to a certain extent.

Income Tax

Oversea Officer on Leave

"LIEUT.-COL. I.M.S. (RET.)" has a house in England. In 1927 he was on six months' leave from India, and spent just over four months of the year 1927–28 in England. He was assessed to tax on the amount of the salary drawn in England, plus £300 brought to England for the purchase of a car and outfit, plus the amount of his oversea pay from October, 1927, to March, 1928, though he was back in India by the end of October, 1927. Was that assessment correct?

*** A *cardinal fact* is that, as our correspondent has a residence in this country, he has to be regarded as a British resident for purposes of taxation. It is therefore clear that he was correctly charged to British income tax on the amount of pay received in this country, and also on the £300, if that sum was remitted (or rather brought) to this country out of income. But we are not clear with regard to the taxation of the pay for the period November to March. If, as we gather, the pay was received abroad in respect of an appointment held from an authority abroad, we should have expected it to be outside the scope of British taxation, and we advise our correspondent to raise the question accordingly with the authorities.

LETTERS, NOTES, ETC.

Varicose Ulceration

Dr. G. A. MOULDEN (Bebington, Cheshire) writes. I have been much interested in the papers on the treatment of varicose ulceration after the method of Dickson Wright, and also in the ensuing correspondence. Dr. Adamson's detailed description of Hunt's method still further confirms the fact that the most important element of treatment is adequate support of the leg. Dr. J. Byrne contributed a paper to the *American Journal of Medical Sciences* (October, 1926), and I have used his method with success since then. Stated briefly, after protection of the surrounding skin by vaseline or a bland ointment, the ulcer is covered by overlapping strips of gutta-percha tissue. Any excess of discharge is allowed exit between the strips. A ring of non absorbent wool is then formed around the edges of the ulcer, and the space inside the ring is lightly packed with absorbent gauze; this ring of wool serves to protect the ulcer itself from bandage pressure, and also gives a little extra pressure to the oedematous edge and surrounding tissues. The whole of the leg, from toes to knee, is now encased in a fairly thick layer of non-absorbent wool, as evenly as possible. Two bandages of unbleached calico, 3 inches wide and 6 yards long, are now fixed firmly to the limb, one after the other. The patient is instructed to remove the top bandage when she gets into bed at night, and to replace it firmly before she gets out of bed in the morning. Any slackening of bandage pressure due to diminution of the oedema is in this way taken up, and firm pressure is thereby maintained. The dressings are changed as little as possible—for example, fortnightly. This method has the advantages of Hunt's bandaging, giving equality of pressure with simplicity. It protects the ulcer from trauma, and leaves it in contact with the discharge. Excess of discharge is taken up by the gauze, and the unpleasantness of a foul bandage is avoided. The pressure of the ring of wool on the edge also helps to expedite healing. Dr. Byrne suggests that the beneficial action of the discharge on the ulcer lies in the tryptic action of the serum, which digests the hard, callous edge of the ulcer, and therefore allows the epithelium to grow inwards.

Bromide Poisoning in a Monkey

Dr. JAMES R. SALMOND (Appleby Magna, Burton-on-Trent) writes: Our young pet drill monkey, weighing 7 lb., last week managed to secure a sample packet of sedobrol which had just been unpacked from the post, and devoured 5½ tablets before dropping the box. Treatment to recover them having failed, he was put outside under observation. At the end of three hours he developed vertigo, staggering gait, and finally spasmodic muscular movements somewhat like chorea, accompanied by threatened syncope. He was kept awake for an hour by massage, handling, and flicking with wet towels, and the collapse was met by amyl nitrite capsules and heat. Finally he became comatose, and could only be revived and the heart's action maintained by hypodermic injections of 1/200 grain of digitaline and strychnine, ½ c.cm. of pituitrin, 15 minim doses of ether, and brandy when he could swallow. On the third day the cortical irritation grew less, and he showed only a few jerky movements of the head, but the constipation became absolute, and tympanitis developed, accompanied by anuria. The heart's action became very feeble, and artificial respiration was resorted to as well as the hypodermic injections, while turpentine stupes were applied all that day, and three enemas (which were retained); he was also given a gastric lavage with potassium permanganate solution. Treatment was continued during the night, but the distension was tremendous, and a 2 grain dose of calomel had no effect. As he was still alive on the fourth day we administered ½ grain of calomel hourly, and a total of 5½ grains was taken before an action took place. This gave relief, and an hour later, although very thin and weak, the patient had recovered sufficiently to steal a banana left near his box. Since then he has made rapid progress, and save for loss of flesh seems little the worse. I understand that the amount of sodium bromide in each sedobrol tablet is about 17 grains, making the total dose taken about 90 grains.

Insurance against Incapacity

"SAFEGUARDED" writes: In a letter which appeared in your issue of January 3rd, appealing for the medical charities, the writer asks: "What is the financial result of an 'accident' or 'sickness' policy to a man suddenly and permanently struck down by trauma, encephalitis, or cerebral lesion?" and he puts the further question, "What proportion of our members can face with equanimity disasters such as these?" I should like, from personal experience, to answer these questions. I was suddenly struck down by such an illness early in 1930, from which, after eleven months, I have happily recovered. During this period the Medical Sickness, Annuity, and Life Assurance Society, Ltd., have paid me £478. Had my incapacity been permanent I would have been entitled to over £300 a year, free of tax, to age 65. Such financial backing is an excellent sedative for any sick and seriously disabled man.

An Index of Proprietary Drugs

Messrs. ROBERTS AND CO. (76, New Bond Street, W.1) have published a third edition of their *Prescriber's List*. This gives concise particulars about the chief medical preparations of their own manufacture and those of foreign origin which are in most frequent demand. The arrangement is alphabetical. A copy will be sent free of charge to any member of the medical profession who has not already received one.

Vacancies

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 58, 59, 60, 61, 65, and 66 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 62, 63, and 64.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 15.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

46 Enteric Fever during the War

A. HANNS (*Rev. d'Hyg. et de Méd. Prév.*, November, 1930, p. 817) states that during the early months of the war the French army was attacked by typhoid fever, but the disease was most prevalent in the Third Army, which chiefly occupied the Argonne. The daily incidence in the whole army was from 400 to 500 cases a day, of which 200 to 250 were in the Third Army alone. The incidence of enteric per 1,000 men at this time was: November, 1914, 6.12; December, 1914, 7.24; January, 1915, 7.0. In February, 1915, the number of cases began to fall, and by June the incidence per 1,000 was only 1.4. This first epidemic, which was cut short chiefly by inoculation on a large scale, was mainly one of typhoid fever. Of 98 positive blood cultures, 93 showed *B. typhosus* and only 5 *B. paratyphosus* B. In July, 1915, a fresh outbreak of enteric fever occurred, the number of cases rising in September to 6,629, but on this occasion was mainly one of paratyphoid, especially of paratyphoid A, the percentage of which was 40.9 in July, 59.3 in August, 76.3 in October, and 92.4 in November. The predominance of paratyphoid infection on this occasion was due to the fact that antityphoid inoculation furnished no protection against paratyphoid infection. A mixed paratyphoid A and B vaccine was then given, and in February, 1916, the incidence of paratyphoid, first of B and then of A, began to fall. In July, 1916, however, a rise in the incidence of typhoid occurred almost entirely among the Third Army, the explanation of this being that the immunity conferred by antityphoid inoculation did not exceed a year. In May, 1916, therefore, a further inoculation was ordered, this time with a complete T.A.B. vaccine; a fall in the incidence began at once, and no further rise occurred during the year. The official percentage figures for the enteric mortality for each year of the war were as follows: 1914 (5 months), 17.97; 1915, 9.77; 1916, 3.82; 1917, 8.15; 1918, 16.5. The fatality of the different epidemics of enteric during the war depended mainly on the distribution of typhoid and paratyphoid. The first epidemic (November, 1914, to April, 1915), in which the fatality ranged from 12.5 to 17.9 per cent., was one of typhoid. The second epidemic (June to September, 1915), which was characterized by a very low death rate—2.5 to 3.53 per cent.—was one of paratyphoid. The third outbreak (July to November, 1916), in which the death rate suddenly rose to 5.6 per cent., was mainly one of typhoid. During the final period (1917 to 1918), when the enteric incidence remained at a constantly low level, the death rate rose to 10–11 per cent., and the majority of the cases were typhoid fever.

47 Late Effects of the Specific Treatment of Syphilis

E. GOTTLIED and N. I. NISSEN (*Ugeskrift for Laeger*, November 6th, 1930, p. 1039) report investigations which do not support the view that there is a connexion between salvarsan treatment and the frequency of syphilitic aortitis. Their cases of aortitis and other diseases of the heart and aorta in patients who had suffered from syphilis had either been treated with mercury alone or had received no specific treatment whatever. Their investigations consisted of a scrutiny of the records of a hospital between November, 1925, and July, 1929. In their first category they put the patients showing late signs of syphilis, clinically or post mortem. In their second category they placed those patients whose only sign of a previous infection was a positive Wassermann reaction. In their third category were those patients who admitted having contracted syphilis, but who no longer showed any signs of it. No case was included in this classification in which the original syphilitic infection dated back less than ten years, since a smaller interval would, generally speaking, be insufficient for the development of demonstrable syphilis of the vascular system. The cases were further classified according to whether they had not received treatment, had been treated with mercury, or had been treated with salvarsan, with or without mercury. Of the 87 patients with late syphilitic lesions, only 2 had been given injections of salvarsan at the beginning of the disease; the remainder had either received no treatment or had been treated most inadequately with mercury. On the other hand, in the third group, among the 31 patients with a history of a previous infection with syphilis, but without any syphilitic manifestations in the period under review, there were as many as 16 who had been treated with salvarsan.

48 Diphtherial Infection of the Umbilicus

J. C. MONTGOMERY (*Amer. Journ. Dis. Child.*, November, 1930, p. 968), who records a personal case and has collected from the literature 42 other examples in which the diagnosis was proved by bacteriological examination, distinguishes three groups of diphtheria of the umbilicus, namely: (1) those with no clinical evidence of infection but affording positive cultures from a moist umbilicus (3 cases); (2) those with a slight caseous deposit and positive cultures (22 cases); and (3) those with more extensive evidence of infection (17 cases). In several instances diphtheria was found in other parts of the body, especially the nose. Montgomery's patient was a male infant who developed some redness round the umbilicus at the age of 3 weeks. This was followed by an area of swelling which gradually reached the size of the palm of the hand. A few days later the skin about the umbilicus presented a brownish-red discoloration, and in the umbilicus there appeared a small fistulous opening; in this a greyish exudate was seen, and from it a growth of virulent diphtheria bacilli was obtained. Death ensued from paralysis of the diaphragm and myocarditis. The author has found no other case on record of diphtheria confined to the umbilicus and associated with myocardial or nervous complications.

49 Chancre of the Tongue

J. VILENSKY (*Thèse de Paris*, 1930, No. 219) states that chancre of the tongue, which was first described by Astruc in 1726, is almost always due to inoculation from mucous tubercles. The modes of infection are either direct (bucco-buccal, bucco-genital, bucco-anal, or bucco-mammary) or, more frequently, indirect. Chancre of the tongue occupies the third place in the list of extragenital chancres, those of the lips and tonsils being the most frequent. It is three to three and a half times more frequent in males than in females, whereas the other extragenital chancres are most frequent in females. The relative frequency of lingual chancre to other extragenital infections is 5 per cent. As a rule lingual chancre is single, but double chancres are not very rare. The age most frequently affected is between 20 and 30. The sites of the tongue affected in order of frequency are the tip, anterior third of the dorsum, base, centre, and sides. The lower surface is rarely involved. Four forms of lingual chancre may be described—namely, ulcerative, hypertrophic, mixed, and phagedaenic. The lesion is only slightly tender, and does not cause much trouble. It must be differentiated from herpes, aphthae, mucous tubercles, the sublingual ulcer of whooping-cough, secondary and tertiary syphilitic ulcers, acute tuberculous ulcers, cancer, tertiary sclerotic glossitis, and dental glossitis. The secondary stage appears unusually early—on the average 25 days after the appearance of the chancre—and is very often characterized by an intense eruption, which shows a predilection for the thorax, arms, neck, and sometimes the face. The

nervous complications of syphilis and the common tertiary manifestations are unusually frequent. Treatment is the same as for syphilis in general, but local treatment is necessary to prevent the spread of the infection.

50 Perlèche in Adults

E. A. SKOLNIK (*Arch. of Derm. and Syph.*, October, 1930, p. 642) records five cases, in adults aged from 41 to 46, of this fissured condition of the angles of the mouth, which usually is confined to children. In each case the disease assumed a chronic form, the shortest duration being three years. The lesions were bilateral, and varied from 7 to 12 mm. in length. All were roughly wedge-shaped, fissured in their long dimension, and showed slight maceration and thickening. There was some scaling of the erythematous areas, which stopped abruptly at the vermilion border of the angles of the mouth. The lesions neither bled nor ulcerated. The patients complained only of a sensation of dryness and of slight pain on opening the mouth widely. Cryptococci were isolated from the lesions in each case, and inoculation of a pure culture of cryptococcus under the normal breast produced a lesion similar to those at the angles of the mouth, which disappeared spontaneously in three or four weeks. Exaggeration of the normal fold at the angle of the mouth by a drooping upper lip apparently contributes to the etiology and chronicity of perlèche.

Surgery

51 Burns in Children

E. C. DAVIDSON (*Minnesota Med.*, November, 1930, p. 775) agrees that the profound metabolic disturbance following severe cutaneous burns is due to toxaemia caused by the absorption of some toxic substance or substances from the burned area. The toxaemia is best combated by a local treatment which would prevent absorption from the site of the burn. Tannic acid accomplishes this by forming more or less stable, insoluble compounds with the burnt tissue. Davidson claims that treatment of burns with this drug, followed by exposure to air, lessens toxaemia, and as an initial dressing the acid is analgesic. Its local astringent effect prevents loss of body fluid, and secondary infection is greatly limited by the absence of a favourable nidus for bacterial growth. Scar-tissue formation is less marked than with other methods; moreover, the protective layer of coagulated protein forms a framework for the growth of young epithelial cells over the denuded area. The prognosis in burns in childhood must be guarded, and depends on the depth rather than the extent of the burns. The clinical course of burns may be divided into four stages: shock, acute toxaemia, septic toxaemia, and healing. In children shock almost invariably occurs. The child should be placed in a light tent on sterile sheets. Blebs should be opened, all loose tissue carefully removed, and the denuded area thoroughly cleansed without excessive traumatism. The burned part is then sprayed with a 5 per cent. aqueous solution of tannic acid every fifteen minutes until the surface is a light brown colour. Normal saline solution should be injected subcutaneously, intravenously, and rectally, and fluids be given by the mouth. If shock threatens, transfusion is performed, and this is repeated if necessary. Intravenous normal saline solution should be injected daily and sedatives be administered at night till the period of toxaemia is past. Since children tolerate granulating wounds very badly, skin grafting should be performed promptly, generally in the third or fourth week. Pinch grafts are advised for large areas. Burns involving the axilla are very important owing to the disability of arm-chest adhesions. This deformity may be largely avoided by keeping the arm in abduction during healing. If webbing occurs the web should be divided high up in the axilla, anterior and posterior flaps be turned into this newly formed axilla, and the lower defect be filled with Thiersch or pinch grafts. The treatment of deformities following old burns is briefly dealt with.

52 Rupture of the Spleen and Left Kidney
